REPORT OF THE NATIONAL CONSERVATION COMMISSION

FEBRUARY
1909

SPECIAL MESSAGE FROM THE PRESIDENT OF THE UNITED STATES

TRANSMITTING A REPORT OF THE
NATIONAL CONSERVATION COMMISSION, WITH ACCOMPANYING PAPERS

IN THREE VOLUMES

VOLUME I

EDITED UNDER THE DIRECTION OF THE EXECUTIVE
COMMITTEE BY HENRY GANNETT

WASHINGTON
GOVERNMENT PRINTING OFFICE
1909

HC101
A4
v.1

SENATE OF THE UNITED STATES,
February 18, 1909.

Resolved, That the special message from the President of the United States, transmitting a report of the National Conservation Commission, with accompanying papers and illustrations, be printed in full as a document, taking number 676 of the present Congress, the number of the document containing the special message of the President transmitting this report.

TABLE OF CONTENTS.

Page.

- Special message of the President 1
- Letter of transmittal of the report to the President 11
- Report of the National Conservation Commission 13
  - Minerals 15
  - Lands 17
  - Forests 19
  - Waters 21
  - National efficiency 25
- Joint conservation conference 27
  - Personnel of the conference 28
- Statements by the Secretaries 37

Water resources—

- What we have 39
- What we use and waste 40
- Where we stand 43
- What we need to do 45

Forests—

- What forests do 51
- What we have 52
- What is produced 54
- What is used 55
- What is wasted 57
- Where we stand 58
- What should be done 60
  - Duty of the private owner 61
  - Economy in the mill 66
  - Task of the States 68
  - The nation's task 69
- Where we might stand 72
- Sources of material 73

Lands—

- The national estate 75

Use and abuse of lands—

- Agricultural industries 75
- Productivity of the soil 76
- Abandoned farms 78
- Necessity for increasing crops 79
- Decline in exports of foodstuffs 80
- Wastes due to noxious insects and mammals 81
- Losses of live stock by disease 81
- Wild game and fur-bearing animals 82
- Fish 82
- The open range 82
- Swamp and overflow lands 83
- Increase in private holdings 84

The public lands—

- Data and policy 85
- Land disposal 86
- Land classification 86
- Timber and stone act 87
- Commutation clause of homestead act 87
- Dry-farming lands 88

Statements by the Secretaries—Continued. Page.

Lands—Continued.

The public lands—Continued.

SPECIAL MESSAGE OF THE PRESIDENT

TRANSMITTING THE

REPORT OF THE NATIONAL CONSERVATION COMMISSION

To the Senate and House of Representatives:

I transmit herewith a report of the National Conservation Commission, together with the accompanying papers. This report, which is the outgrowth of the conference of governors last May, was unanimously approved by the recent joint conference held in this city between the National Conservation Commission and governors of States, state conservation commissions, and conservation committees of great organizations of citizens. It is therefore in a peculiar sense representative of the whole nation and all its parts.

With the statements and conclusions of this report I heartily concur, and I commend it to the thoughtful consideration both of the Congress and of our people generally. It is one of the most fundamentally important documents ever laid before the American people. It contains the first inventory of its natural resources ever made by any nation. In condensed form it presents a statement of our available capital in material resources, which are the means of progress, and calls attention to the essential conditions upon which the perpetuity, safety, and welfare of this nation now rest and must always continue to rest. It deserves, and should have, the widest possible distribution among the people.

The facts set forth in this report constitute an imperative call to action. The situation they disclose demands that we, neglecting for a time, if need be, smaller and less vital questions, shall concentrate an effective part of our attention upon the great material foundations of national existence, progress, and prosperity.

This first inventory of natural resources prepared by the National Conservation Commission is undoubtedly but the beginning of a series which will be indispensable for dealing intelligently with what we have. It supplies as close an approximation to the actual facts as it was possible to prepare with the knowledge and time available. The progress of our knowledge of this country will continually lead to more accurate information and better use of the sources of national strength. But we can not defer action until complete accuracy in the estimates can be reached, because before that time many of our resources will be practically gone. It is not necessary that this inventory should be exact in every minute detail. It is essential that it should correctly describe the general situation; and that the present inventory does. As it stands it is an irrefutable proof that the conservation of our resources is the fundamental question before this nation, and that our first and greatest task is to set our house in order and begin to live within our means.

The first of all considerations is the permanent welfare of our people; and true moral welfare, the highest form of welfare, can not permanently exist save on a firm and lasting foundation of material well-being. In this respect ~~our~~ situation is far from satisfactory. After every possible allowance has been made, and when every hopeful indication has beeen given its full weight, the facts still give reason for grave concern. It would be unworthy of our history and our intelligence, and disastrous to our future, to shut our eyes to these facts or attempt to laugh them out of court. The people should and will rightly demand that the great fundamental questions shall be given attention by their representatives. I do not advise hasty or ill-considered action on disputed points, but I do urge, where the facts are known, where the public interest is clear, that neither indifference and inertia, nor adverse private interests, shall be allowed to stand in the way of the public good.

The great basic facts are already well known. We know that our population is now adding about one-fifth to its numbers in ten years, and that by the middle of the present century perhaps one hundred and fifty million Americans, and by its end very many millions more, must be fed and clothed from the products of our soil. With the steady growth in population and the still more rapid increase in consumption, our people will hereafter make greater and not less demands per capita upon all the natural resources for their livelihood, comfort, and convenience. It is high time to realize that our responsibility to the coming millions is like that of parents to their children, and that in wasting our resources we are wronging our descendants.

We know now that our rivers can and should be made to serve our people effectively in transportation, but that the vast expenditures for our waterways have not resulted in maintaining, much less in promoting, inland navigation. Therefore, let us take immediate steps to ascertain the reasons and to prepare and adopt a comprehensive plan for inland-waterway navigation that will result in giving the people the benefits for which they have paid but which they have not yet received. We know now that our forests are fast disappearing, that less than one-fifth of them are being conserved, and that no good purpose can be met by failing to provide the relatively small sums needed for the protection, use, and improvement of all forests still owned by the Government, and to enact laws to check the wasteful destruction of the forests in private hands. There are differences of opinion as to many public questions; but the American people stand nearly as a unit for waterway development and for forest protection.

We know now that our mineral resources once exhausted are gone forever, and that the needless waste of them costs us hundreds of human lives and nearly $300,000,000 a year. Therefore, let us undertake without delay the investigations necessary before our people will be in position, through state action or otherwise, to put an end to this huge loss and waste, and conserve both our mineral resources and the lives of the men who take them from the earth.

I desire to make grateful acknowledgment to the men, both in and out of the government service, who have prepared the first inventory of our natural resources. They have made it possible for this nation to take a great step forward. Their work is helping us to see that the greatest questions before us are not partisan questions, but questions upon which men of all parties and all shades of opinion may be united for the common good. Among such questions, on the material side, the conservation of natural resources stands first. It is the bottom round of the ladder on our upward progress toward a condition in which the nation as a whole, and its citizens as individuals, will set national efficiency and the public welfare before personal profit.

The policy of conservation is perhaps the most typical example of the general policies which this Government has made peculiarly its own during the opening years of the present century. The function of our Government is to insure to all its citizens, now and hereafter, their rights to life, liberty, and the pursuit of happiness. If we of this generation destroy the resources from which our children would otherwise derive their livelihood, we reduce the capacity of our land to support a population, and so either degrade the standard of living or deprive the coming generations of their right to life on this continent. If we allow great industrial organizations to exercise unregulated control of the means of production and the necessaries of life, we deprive the Americans of to-day and of the future of industrial liberty, a right no less precious and vital than political freedom. Industrial liberty was a fruit of political liberty, and in turn has become one of its chief supports, and exactly as we stand for political democracy so we must stand for industrial democracy.

The rights to life and liberty are fundamental, and like other fundamental necessities, when once acquired, they are little dwelt upon. The right to the pursuit of happiness is the right whose presence or absence is most likely to be felt in daily life. In whatever it has accomplished, or failed to accomplish, the administration which is just drawing to a close has at least seen clearly the fundamental need of freedom of opportunity for every citizen. We have realized that the right of every man to live his own life, provide for his family, and endeavor, according to his abilities, to secure for himself and for them a fair share of the good things of existence, should be subject to one limitation and to no other. The freedom of the individual should be limited only by the present and future rights, interests, and needs of the other individuals who make up the community. We should do all in our power to develop and protect individual liberty, individual initiative, but subject always to the need of preserving and promoting the general good. When necessary, the private right must yield, under due process of law and with proper compensation, to the welfare of the commonwealth. The man who serves the community greatly should be greatly rewarded by the community; as there is great inequality of service, so there must be great inequality of reward; but no man and no set of men should be allowed to play the game of competition with loaded dice.

All this is simply good common sense. The underlying principle of conservation has been described as the application of common sense to common problems for the common good. If the description is correct, then conservation is the great fundamental basis for national efficiency. In this stage of the world's history, to be fearless, to be just, and to be efficient are the three great requirements of national life. National efficiency is the result of natural resources well handled, of freedom of opportunity for every man, and of the inherent capacity, trained ability, knowledge, and will, collectively and individually, to use that opportunity.

This administration has achieved some things; it has sought, but has not been able, to achieve others; it has doubtless made mistakes; but all it has done or attempted has been in the single, consistent effort to secure and enlarge the rights and opportunities of the men and women of the United States. We are trying to conserve what is good in our social system, and we are striving toward this end when we endeavor to do away with what is bad. Success may be made too hard for some if it is made too easy for others. The rewards of common industry and thrift may be too small if the rewards for other, and on the whole less valuable, qualities, are made too large, and especially if the rewards for qualities which are really, from the public standpoint, undesirable are permitted to become too large. Our aim is so far as possible to provide such conditions that there shall be equality of opportunity where there is equality of energy, fidelity, and intelligence; when there is a reasonable equality of opportunity the distribution of rewards will take care of itself.

The unchecked existence of monopoly is incompatible with equality of opportunity. The reason for the exercise of government control over great monopolies is to equalize opportunity. We are fighting against privilege. It was made unlawful for corporations to contribute money for election expenses in order to abridge the power of special privilege at the polls. Railroad-rate control is an attempt to secure an equality of opportunity for all men affected by rail transportation; and that means all of us. The great anthracite coal strike was settled, and the pressing danger of a coal famine averted, because we recognized that the control of a public necessity involves a duty to the people, and that public intervention in the affairs of a public-service corporation is neither to be resented as usurpation nor permitted as a privilege by the corporations, but on the contrary to be accepted as a duty and exercised as a right by the Government in the interest of all the people. The efficiency of the army and the navy has been increased so that our people may follow in peace the great work of making this country a better place for Americans to live in, and our navy was sent round the world for the same ultimate purpose. All the acts taken by the Government during the last seven years, and all the policies now being pursued by the Government, fit in as parts of a consistent whole.

Our public-land policy has for its aim the use of the public land so that it will promote local development by the settlement of home makers; the policy we champion is to serve all the people legitimately and openly, instead of permitting the lands to be converted, illegitimately and under cover, to the private benefit of a few. Our forest policy was established so that we might use the public forests for the permanent public good, instead of merely for temporary private gain. The reclamation act, under which the desert parts of the public domain are converted to higher uses for the general benefit, was passed so that more Americans might have homes on the land.

These policies were enacted into law and have justified their enactment. Others have failed, so far, to reach the point of action. Among such is the attempt to secure public control of the open range, and thus to convert its benefits to the use of the small man, who is the home maker, instead of allowing it to be controlled by a few great cattle and sheep owners.

The enactment of a pure-food law was a recognition of the fact that the public welfare outweighs the right to private gain, and that no man may poison the people for his private profit. The employers' liability bill recognized the controlling fact that while the employer usually has at stake no more than his profit, the stake of the employee is a living for himself and his family.

We are building the Panama Canal; and this means that we are engaged in the giant engineering feat of all time. We are striving to add in all ways to the habitability and beauty of our country. We are striving to hold in the public hands the remaining supply of unappropriated coal, for the protection and benefit of all the people. We have taken the first steps toward the conservation of our natural resources, and the betterment of country life, and the improvement of our waterways. We stand for the right of every child to a childhood free from grinding toil, and to an education; for the civic responsibility and decency of every citizen; for prudent foresight in public matters, and for fair play in every relation of our national and economic life. In international matters we apply a system of diplomacy which puts the obligations of international morality on a level with those that govern the actions of an honest gentleman in dealing with his fellow-men. Within our own border we stand for truth and honesty in public and in private life, and war sternly against wrongdoers of every grade. All these efforts are integral parts of the same attempt, the attempt to enthrone justice and righteousness, to secure freedom of opportunity to all of our citizens, now and hereafter, and to set the ultimate interest of all of us above the temporary interest of any individual, class, or group.

The nation, its government, and its resources exist, first of all, for the American citizen, whatever his creed, race, or birthplace, whether he be rich or poor, educated or ignorant, provided only that he is a good citizen, recognizing his obligations to the nation for the rights and opportunities which he owes to the nation.

The obligations, and not the rights, of citizenship increase in proportion to the increase of a man's wealth or power. The time is coming when a man will be judged, not by what he has succeeded in getting for himself from the common store, but by how well he has done his duty as a citizen, and by what the ordinary citizen has gained in freedom of opportunity because of his service for the common good. The highest value we know is that of the individual citizen, and the highest justice is to give him fair play in the effort to realize the best there is in him.

The tasks this nation has to do are great tasks. They can only be done at all by our citizens acting together, and they can be done best of all by the direct and simple application of homely common sense.

The application of common sense to common problems for the common good, under the guidance of the principles upon which this republic was based, and by virtue of which it exists, spells perpetuity for the nation, civil and industrial liberty for its citizens, and freedom of opportunity in the pursuit of happiness for the plain American, for whom this nation was founded, by whom it was preserved, and through whom alone it can be perpetuated. Upon this platform—larger than party differences, higher than class prejudice, broader than any question of profit and loss—there is room for every American who realizes that the common good stands first.

The National Conservation Commission wisely confined its report to the statement of facts and principles, leaving the Executive to recommend the specific steps to which these facts and principles inevitably lead. Accordingly, I call your attention to some of the larger features of the situation disclosed by the report, and to the action thereby clearly demanded for the general good.

WATERS.

The report says:

> Within recent months it has been recognized and demanded by the people, through many thousand delegates from all States assembled in convention in different sections of the country, that the waterways should and must be improved promptly and effectively as a means of maintaining national prosperity.
>
> The first requisite for waterway improvement is the control of the waters in such manner as to reduce floods and regulate the regimen of the navigable rivers. The second requisite is development of terminals and connections in such manner as to regulate commerce.

Accordingly, I urge that the broad plan for the development of our waterways recommended by the Inland Waterways Commission be put in effect without delay. It provides for a comprehensive system of waterway improvement extending to all the uses of the waters and benefits to be derived from their control, including navigation, the development of power, the extension of irrigation, the drainage of swamp and overflow lands, the prevention of soil wash, and the purification of streams for water supply. It proposes to carry out the work by coordinating agencies in the federal departments through the medium of an administrative commission or board, acting in cooperation with the States and other organizations and individual citizens.

The work of waterway development should be undertaken without delay. Meritorious projects in known conformity with the general outlines of any comprehensive plan should proceed at once. The cost of the whole work should be met by direct appropriation if possible, but if necessary by the issue of bonds in small denominations.

It is especially important that the development of water power should be guarded with the utmost care both by the National Government and by the States in order to protect the people against the upgrowth of monopoly and to insure to them a fair share in the benefits which will follow the development of this great asset which belongs to the people and should be controlled by them.

FORESTS.

I urge that provision be made for both protection and more rapid development of the national forests. Otherwise, either the increasing use of these forests by the people must be checked or their protection against fire must be dangerously weakened. If we compare the actual fire damage on similar areas on private and national forest lands during the past year, the government fire patrol saved commercial timber worth as much as the total cost of caring for all national forests at the present rate for about ten years.

I especially commend to the Congress the facts presented by the commission as to the relation between forests and stream flow in its bearing upon the importance of the forest lands in national ownership. Without an understanding of this intimate relation the conservation of both these natural resources must largely fail.

The time has fully arrived for recognizing in the law the responsibility to the community, the State, and the nation which rests upon the private owners of private lands. The ownership of forest land is a public trust. The man who would so handle his forest as to cause erosion and to injure stream flow must be not only educated, but he must be controlled.

The report of the National Conservation Commission says:

> Forests in private ownership can not be conserved unless they are protected from fire. We need good fire laws, well enforced. Fire control is impossible without an adequate force of men whose sole duty is fire patrol during the dangerous season.

I hold as first among the tasks before the States and the nation in their respective shares in forest conservation the organization of efficient fire patrols and the enactment of good fire laws on the part of the States.

The report says further:

> Present tax laws prevent reforestation of cut-over land and the perpetuation of existing forests by use. An annual tax upon the land itself, exclusive of the timber, and a tax upon the timber when cut is well adapted to actual conditions of forest investment and is practicable and certain. It is far better that forest land should pay a moderate tax permanently than that it should pay an excessive revenue temporarily and then cease to yield at all.

Second only in importance to good fire laws well enforced is the enactment of tax laws which will permit the perpetuation of existing forests by use.

LANDS.

With our increasing population the time is not far distant when the problem of supplying our people with food will become pressing. The possible additions to our arable area are not great, and it will become necessary to obtain much larger crops from the land, as is now done in more densely settled countries. To do this, we need better farm practice and better strains of wheat, corn, and other crop plants, with a reduction in losses from soil erosion and from insects, animals, and other enemies of agriculture. The United States Department of Agriculture is doing excellent work in these directions, and it should be liberally supported.

The remaining public lands should be classified and the arable lands disposed of to home makers. In their interest the timber and stone act and the commutation clause of the homestead act should be repealed, and the desert-land law should be modified in accordance with the recommendations of the Public Lands Commission.

The use of the public grazing lands should be regulated in such ways as to improve and conserve their value.

Rights to the surface of the public land should be separated from rights to forests upon it and to minerals beneath it, and these should be subject to separate disposal.

The coal, oil, gas, and phosphate rights still remaining with the Government should be withdrawn from entry and leased under conditions favorable for economic development.

MINERALS.

The accompanying reports show that the consumption of nearly all of our mineral products is increasing more rapidly than our population. Our mineral waste is about one-sixth of our product, or nearly $1,000,000 for each working day in the year. The loss of structural materials through fire is about another million a day. The loss of life in the mines is appalling. The larger part of these losses of life and property can be avoided.

Our mineral resources are limited in quantity and can not be increased or reproduced. With the rapidly increasing rate of consumption the supply will be exhausted while yet the nation is in its infancy unless better methods are devised or substitutes are found. Further investigation is urgently needed in order to improve methods and to develop and apply substitutes.

It is of the utmost importance that a bureau of mines be established in accordance with the pending bill to reduce the loss of life in mines and the waste of mineral resources and to investigate the methods and substitutes for prolonging the duration of our mineral supplies. Both the need and the public demand for such a bureau are rapidly becoming more urgent. It should cooperate with the States in supplying data to serve as a basis for state mine regulations. The establishment of this bureau will mean merely the transfer from other bureaus of work which it is agreed should be transferred and slightly enlarged and reorganized for these purposes.

CONCLUSIONS.

The joint conference already mentioned adopted two resolutions to which I call your special attention. The first was intended to promote cooperation between the States and the nation upon all of the great questions here discussed. It is as follows:

> *Resolved*, That a joint committee be appointed by the chairman, to consist of six members of state conservation commissions and three members of the National Conservation Commission, whose duty it shall be to prepare and present to the state and national commissions, and through them to the governors and the President, a plan for united action by all organizations concerned with the conservation of natural resources.
>
> (On motion of Governor Noel, of Mississippi, the chairman and secretary of the conference were added to and constituted a part of this committee.)

The second resolution of the joint conference to which I refer calls upon the Congress to provide the means for such cooperation. The principle of the community of interest among all our people in the great natural resources runs through the report of the National Conservation Commission and the proceedings of the joint conference. These resources, which form the common basis of our welfare, can be wisely developed, rightly used, and prudently conserved only by the common action of all the people, acting through their representatives in State and nation. Hence the fundamental necessity for cooperation. Without it we shall accomplish but little, and that little badly. The resolution follows:

> We also especially urge on the Congress of the United States the high desirability of maintaining a national commission on the conservation of the resources of the country, empowered to cooperate with state commissions to the end that every sovereign commonwealth and every section of the country may attain the high degree of prosperity and the sureness of perpetuity naturally arising in the abundant resources and the vigor, intelligence, and patriotism of our people.

In this recommendation I most heartily concur, and I urge that an appropriation of at least $50,000 be made to cover the expenses of the National Conservation Commission for necessary rent, assistance, and traveling expenses. This is a very small sum. I know of no other way in which the appropriation of so small a sum would result in so large a benefit to the whole nation.

THEODORE ROOSEVELT.

THE WHITE HOUSE, *January 22, 1909.*

LETTER OF THE CHAIRMAN OF THE NATIONAL CONSERVATION COMMISSION

TRANSMITTING THE

REPORT TO THE PRESIDENT

NATIONAL CONSERVATION COMMISSION,
Washington, January 11, 1909.

SIR: Herewith I have the honor to place in your hands the report of the National Conservation Commission, created by you June 8, 1908, to inquire into and advise you as to the condition of our natural resources, and to cooperate with other bodies created for similar purposes by the States.

The executive committee designated in your letter creating the commission organized on June 19 and outlined a plan for making an inventory of the natural resources of the United States. On July 1 work was undertaken, accordingly, with the cooperation of the bureaus of the federal departments, authorities of the different States, and representative bodies of the national industries. The results of this cooperative work are herewith submitted as appendixes of the commission's report.

The mass of material which constitutes the inventory has been summarized under the direction of the secretaries of the respective sections of the commission so as to assemble the most salient points of the inventory. At the first general meeting of the commission, on December 1, 1908, the summaries of the four sections of the commission were presented and were supplemented by personal statements of the experts in the several bureaus in the executive departments who had immediate charge of the inventory along their special lines of work. After the discussion of the summaries and statements the commission united in the report which is herewith submitted.

In view of the peculiarly valuable contributions and services rendered by the experts of the several departments, the commission at its closing session unanimously adopted the following resolutions:

> Whereas the commission, in the discharge of the duties committed to it, has been greatly aided by the patient labors and the ability and zeal of its secretary and the secretary of each of its four sections, and of the experts in the government service who lent their assistance in the collection of statistical and other data necessary to the elucidation and proper understanding of the subjects dealt with, and to the preparation of its report: Therefore
>
> *Resolved*, That the commission hereby makes cordial acknowledgment of its obligation to the gentlemen referred to and tenders them its thanks.
>
> *Resolved further*, That the secretary of the commission be directed to transmit to each of those who prepared papers and who appeared before the commission a copy of these resolutions.

In addition, I desire to call your special attention to the spirit and devotion of the gentlemen without whose services the making of the national inventory would have been impossible. Through their great interest in the task intrusted by you to the commission and to them, a great part of their work in connection with the inventory was performed outside the official hours. Furthermore, the material which they have prepared presents valuable information in connection with the work of the several executive departments which otherwise would not have been collected at this time. The assembling of this vast amount of material is largely due to Mr. Henry Gannett, whom you designated for this work, and to whose expert knowledge and power of generalization the commission owes more than it can repay.

In its cooperation "with other bodies created for similar purposes by the States," the National Conservation Commission has had most valuable assistance. Within the first month after the creation of the commission, the governors of 5 States had appointed conservation commissions, and an equal number of organizations of national scope had named conservation committees. At the time of the recent joint conservation conference 33 States and Territories had formed conservation commissions. The number has now increased to 36, with indications that nearly all of the remaining States will soon take similar action. The number of national organizations which have appointed conservation committees is 41.

The report herewith submitted was unanimously approved by the joint conservation conference. Further action was taken by the conference in authorizing a joint committee on cooperation, to be composed of six members of state conservation commissions and three members of the National Conservation Commission with its chairman and secretary. This committee is to devise ways and means for effective cooperation between all forces working for the conservation of natural resources. By this action the conservation movement enters the field of definite constructive work, for which its labors in ascertaining the country's present status and future outlook were simply preparatory.

Very respectfully,

GIFFORD PINCHOT,
Chairman.

The PRESIDENT,
The White House.

REPORT OF THE NATIONAL CONSERVATION COMMISSION

The duty of man to man, on which the integrity of nations must rest, is no higher than the duty of each generation to the next; and the obligation of the nation to each actual citizen is no more sacred than the obligation to the citizen to be, who, in turn, must bear the nation's duties and responsibilities.

In this country, blessed with natural resources in unsurpassed profusion, the sense of responsibility to the future has been slow to awaken. Beginning without appreciation of the measure or the value of natural resources other than land with water for commercial uses, our forefathers pushed into the wilderness and, through a spirit of enterprise which is the glory of the nation, developed other great resources. Forests were cleared away as obstacles to the use of the land; iron and coal were discovered and developed, though for years their presence added nothing to the price of the land; and through the use of native woods and metals and fuels, manufacturing grew beyond all precedent, and the country became a power among the nations of the world.

Gradually the timber growing on the ground and the iron and coal within the ground came to have a market value and were bought and sold as sources of wealth. Meanwhile, vast holdings of these resources were acquired by those of greater foresight than their neighbors before it was generally realized that they possessed value in themselves; and in this way large interests, assuming monopolistic proportions, grew up, with greater enrichment to their holders than the world had seen before, and with the motive of immediate profit, with no concern for the future or thought of the permanent benefit of country and people, a wasteful and profligate use of the resources began and has continued.

The waters, at first recognized only as aids to commerce in supplying transportation routes, were largely neglected. In time this neglect began to be noticed, and along with it the destruction and approaching exhaustion of the forests. This, in turn, directed attention to the rapid depletion of the coal and iron deposits and the misuse of the land.

The public conscience became awakened. Seeing the increased value and noting the destructive consumption and waste of the natural resources, men began to realize that the permanent welfare of the country as well as the prosperity of their offspring were at stake.

The newly awakened sense of duty found expression in a call by the President upon the governors of the States to meet him in conference, and in the declaration of this conference at its sessions in the White House in May, 1908. The action of the conference led to the appointment of the National Conservation Commission, with authority to collect information and cooperate with similar commissions appointed by the States in the great work of conserving the natural resources of the country.

In the growth of the country and gradual development of the natural resources there have been three noteworthy stages. The first stage was that of individual enterprise for personal and family benefit. It led to the conquest of the wilderness.

The next stage was that of collective enterprise, either for the benefit of communities or for the profit of individuals forming the communities. It led to the development of cities and States, and too often to the growth of great monopolies.

The third stage is the one we are now entering. Within it the enterprise is collective and largely cooperative, and should be directed toward the larger benefit of communities, States, and the people generally.

In the first stage the resources received little thought. In the second they were wastefully used. In the stage which we are entering wise and beneficial uses are essential, and the checking of waste is absolutely demanded.

Although the natural resources are interrelated they are unlike, and each class requires distinct treatment. The land is a fixed quantity which can not be materially increased, though its productivity and availability for the uses of man may be greatly augmented; the forests are variable in quantity and may be destroyed by fire, waste, and improvident use, or protected and improved in such way as to meet human necessities. Together the lands and the forests are improvable resources.

The minerals are limited in quantity and can not be increased or improved by anything which man may do. They are expendable resources.

The fresh waters are limited in quantity, though the supply is permanent. They form a naturally renewable resource which man may do nothing to increase, but may do much in the way of conservation and better utilization.

The treatment applied to each class should be adapted to its own fullest development and best utilization and to those of the other classes of resources.

The wastes which most urgently require checking vary widely in character and amount. The most reprehensible waste is that of destruction, as in forest fires, uncontrolled flow of gas and oil, soil wash, and abandonment of coal in the mines. This is attributable, for the most part, to ignorance, indifference, or false notions of economy, to rectify which is the business of the people collectively.

Nearly as reprehensible is the waste arising from misuse, as in the consumption of fuel in furnaces and engines of low efficiency, the loss of water in floods, the employment of ill-adapted structural materials, the growing of ill-chosen crops, and the perpetuation of inferior stocks of plants and animals, all of which may be remedied.

Reprehensible in less degree is the waste arising from nonuse. Since the utilization of any one resource is necessarily progressive and dependent on social and industrial conditions and the concurrent development of other resources, nonuse is sometimes unavoidable.

It becomes reprehensible when it affects the common welfare and entails future injury. Then, it should be rectified in the general interest.

For the prevention of waste the most effective means will be found in the increase and diffusion of knowledge, from which is sure to result an aroused public sentiment demanding prevention. The people have the matter in their own hands. They may prevent or limit the destruction of resources and restrain misuse through the enactment and enforcement of appropriate state and federal laws.

At every stage in the growth of our country, strong men grew stronger through the exercise of nation building, and their intelligence and patriotism grew with their strength. The spirit and vigor of our people are the chief glory of the republic. Yet even as we have neglected our natural resources, so have we been thoughtless of life and health. Too long have we overlooked that grandest of our resources, human life. Natural resources are of no avail without men and women to develop them, and only a strong and sound citizenship can make a nation permanently great. We can not too soon enter on the duty of conserving our chief source of strength by the prevention of disease and the prolongation of life.

Wastes reduced and resources saved are the first but not the last object of conservation. The material resources have an additional value when their preservation adds to the beauty and habitability of the land. Ours is a pleasant land in which to dwell. To increase its beauty and augment its fitness can not but multiply our pleasure in it and strengthen the bonds of our attachment.

In the conservation of all the resources of the country the interest of the present and all future generations is concerned, and in this great work—involving the welfare of the citizen, the family, the community, the state, and the nation—our dual system of government, state and federal, should be brought into harmonious cooperation and collaboration.

MINERALS.

The mineral production of the United States for 1907 exceeded $2,000,000,000, and contributed 65 per cent of the total freight traffic of the country. The waste in the extraction and treatment of mineral products during the same year was equivalent to more than $300,000,000.

The production for 1907 included 395,000,000 tons of bituminous and 85,000,000 tons of anthracite coal, 166,000,000 barrels of petroleum, 52,000,000 tons of iron ore, 2,500,000 tons of phosphate rock, and 869,000,000 pounds of copper. The values of other mineral products during the same year included clay products, $162,000,000; stone, $71,000,000; cement, $56,000,000; natural gas, $53,000,000; gold, $90,000,000; silver, $37,000,000; lead, $39,000,000, and zinc, $26,000,000.

The available and easily accessible supplies of coal in the United States aggregate approximately 1,400,000,000,000 tons. At the present increasing rate of production this supply will be so depleted as to approach exhaustion before the middle of the next century.

The known supply of high-grade iron ores in the United States approximates 4,788,150,000 tons, which at the present increasing rate of consumption can not be expected to last beyond the middle of the present century. In addition to this, there are assumed to be 75,116,070,000 tons of lower grade iron ores which are not available for use under existing conditions.

The supply of stone, clay, cement, lime, sand, and salt is ample, while the stock of the precious metals and of copper, lead, zinc, sulphur, asphalt, graphite, quicksilver, mica, and the rare metals can not well be estimated, but is clearly exhaustible within one to three centuries unless unexpected deposits be found.

The known supply of petroleum is estimated at 15,000,000,000 to 20,000,000,000 barrels, distributed through six separate fields having an aggregate area of 8,900 square miles. The production is rapidly increasing, while the wastes and the loss through misuse are enormous. The supply can not be expected to last beyond the middle of the present century.

The known natural-gas fields aggregate an area of 9,000 square miles, distributed through 22 States. Of the total yield from these fields during 1907, 400,000,000,000 cubic feet, valued at $62,000,000, were utilized, while an equal quantity was allowed to escape into the air. The daily waste of natural gas—the most perfect known fuel—is over 1,000,000,000 cubic feet, or enough to supply every city in the United States of over 100,000 population.

Phosphate rock, used for fertilizer, represents the slow accumulation of organic matter during past ages. In most countries it is scrupulously preserved; in this country it is extensively exported, and largely for this reason its production is increasing rapidly. The original supply can not long withstand the increasing demand.

The consumption of nearly all our mineral products is increasing far more rapidly than our population. In many cases the waste is increasing more rapidly than the number of our people. In 1776 but a few dozen pounds of iron were in use by the average family; now our annual consumption of high-grade ore is over 1,200 pounds per capita. In 1812 no coal was used; now the consumption is over 5 tons and the waste nearly 3 tons per capita.

While the production of coal is increasing enormously, the waste and loss in mining are diminishing. At the beginning of our mineral development the coal abandoned in the mine was two or three times the amount taken out and used. Now the mine waste averages little more than half the amount saved. The chief waste is in imperfect combustion in furnaces and fire boxes. Steam engines utilize on the average about 8 per cent of the thermal energy of the coal. Internal-combustion engines utilize less than 20 per cent, and in electric lighting far less than 1 per cent of the thermal energy is rendered available.

With increasing industries new mineral resources become available from time to time. Some lignites and other low-grade coals are readily gasified and, through the development of internal-combustion engines may be made to check the consumption of high-grade coals.

Peat is becoming important; it is estimated that 14,000,000,000 tons are available in the United States. Its value is enhanced because of distribution through States generally remote from the fields of coal, oil, and natural gas.

The uses of all our mineral resources are interdependent. This is especially true of coal and iron, of which neither can be produced or used without aid from the other, and in the production or reduction of all other minerals both coal and iron are employed. The same standard minerals are necessary to the development of power, of which the use is increasing more rapidly than that of any other commodity.

The building operations of the country now aggregate about $1,000,000,000 per year. The direct and indirect losses from fire in the United States during 1907 approximated $450,000,000, or one-half the cost of construction. Of this loss four-fifths, or an average of $1,000,000 per day, could be prevented, as shown by comparison with the standards of construction and fire losses in the larger European countries.

So far as the ores are taken from the mines and reduced to metals, these resources are capitalized; but after thus being changed to a more valuable form they should be so used as to reduce to a minimum the loss by rust, electrolytic action, and other wastes.

There is urgent need for greater safety to the miner. The loss of life through mine accidents is appalling, and preventive measures can not be taken too soon.

The National Government should exercise such control of the mineral fuels and phosphate rocks now in its possession as to check waste and prolong our supply.

While the distribution and quantity of most of our important mineral substances are known in a general way, there is imperative need for further surveys and investigations and for researches concerning the less-known minerals.

LANDS.

The total land area of continental United States is 1,920,000,000 acres. Of this but little more than two-fifths is in farms, and less than one-half of the farm area is improved and made a source of crop production. We have nearly 6,000,000 farms; they average 146 acres each. The value of the farms is nearly one-fourth the wealth of the United States. There are more than 300,000,000 acres of public grazing land. The number of persons engaged in agricultural pursuits is more than 10,000,000.

We grow one-fifth of the world's wheat crop, three-fifths of its cotton crop, and four-fifths of its corn crop. We plant nearly 50,000,000 acres of wheat annually, with an average yield of about 14 bushels per acre; 100,000,000 acres of corn, yielding an average of 25 bushels per acre; and 30,000,000 acres of cotton, yielding about 12,000,000 bales.

We had on January 1, 1908, 71,000,000 cattle, worth $1,250,000,000; 54,000,000 sheep, worth $211,000,000; and 56,000,000 swine, worth $339,000,000. The census of 1900 showed $137,000,000 worth of poultry in this country, which produced in 1899, 293,000,000 dozen eggs.

There has been a slight increase in the average yield of our great staple farm products, but neither the increase in acreage nor the yield per acre has kept pace with our increase in population. Within a century we shall probably have to feed three times as many people as now; and the main bulk of our food supply must be grown on our own soil.

The area of cultivated land may possibly be doubled. In addition to the land awaiting the plow, 75,000,000 acres of swamp land can be reclaimed, 40,000,000 acres of desert land irrigated, and millions of acres of brush and wooded land cleared. Our population will increase continuously, but there is a definite limit to the increase of our cultivated acreage. Hence we must greatly increase the yield per acre. The average yield of wheat in the United States is less than 14 bushels per acre, in Germany 28 bushels, and in England 32 bushels. We get 30 bushels of oats per acre, England nearly 45, and Germany more than 47. Our soils are fertile, but our mode of farming neither conserves the soil nor secures full crop returns. Soil fertility need not be diminished, but may be increased. The large yields now obtained from farms in Europe which have been cultivated for a thousand years prove this conclusively. Proper management will double our average yield per acre. The United States can grow the farm products needed by a population more than three times as great as our country now contains.

The greatest unnecessary loss of our soil is preventable erosion. Second only to this is the waste, nonuse, and misuse of fertilizer derived from animals and men.

The losses to farm products due to injurious mammals is estimated at $130,000,000 annually; the loss through plant diseases reaches several hundred million dollars; and the loss through insects is reckoned at $659,000,000. The damage by birds is balanced by their beneficent work in destroying noxious insects. Losses due to the elements are large, but no estimate has been made of them. Losses to live stock from these causes are diminishing because of protection and feeding during winter. The annual losses from disease among domestic animals are: Horses, 1.8 per cent; cattle, 2 per cent; sheep, 2.2 per cent, and swine, 5.1 per cent. Most of these farm losses are preventable.

There is a tendency toward consolidation of farm lands. The estimated area of abandoned farms is 16,000 square miles, or about 3 per cent of the improved land. The causes of abandonment differ in different parts of the country. Where most prevalent, it is caused principally by erosion and exhaustion of the soil.

The product of the fisheries of the United States has an annual value of $57,000,000. Fish culture is carried on by the nation and the States on an enormous scale. Most of the more important food species are propagated, and several species are maintained in that way. Fish from forest waters furnish $21,000,000 worth of food yearly, a supply dependent on the preservation of the forests.

Our wild game and fur-bearing animals have been largely exterminated. To prevent their complete extinction the States and the United States have taken in hand their protection, and their numbers are now increasing. Forest game yields over $10,000,000 worth of food each year.

With game birds the story is much the same—wanton destruction until the number has been greatly reduced, followed in recent years by wise protection, which in some cases allows the remnant to survive and even to increase.

Each citizen of the United States owns an equal undivided interest in about 387,000,000 acres of public lands, exclusive of Alaska and the insular possessions. Besides this there are about 235,000,000 acres of national forests, national parks, and other lands devoted to public use.

Good business sense demands that a definite land policy be formulated. The National Conservation Commission believes that the following will serve as a basis therefor:

1. Every part of the public lands should be devoted to the use which will best subserve the interests of the whole people.
2. The classification of all public lands is necessary for their administration in the interests of the people.
3. The timber, the minerals, and the surface of the public lands should be disposed of separately.
4. Public lands more valuable for conserving water supply, timber, and natural beauties or wonders than for agriculture should be held for the use of the people from all except mineral entry.
5. Title to the surface of the remaining nonmineral public lands should be granted only to actual home makers.
6. Pending the transfer of title to the remaining public lands they should be administered by the Government and their use should be allowed in a way to prevent or control waste and monopoly.

The present public-land laws as a whole do not subserve the best interests of the nation. They should be modified so far as may be required to bring them into conformity with the foregoing outline of policy.

FORESTS.

Next to our need of food and water comes our need of timber.

Our industries which subsist wholly or mainly upon wood pay the wages of more than 1,500,000 men and women.

Forests not only grow timber, but they hold the soil and they conserve the streams. They abate the wind and give protection from excessive heat and cold. Woodlands make for the fiber, health, and happiness of the citizen and the nation.

Our forests now cover 550,000,000 acres, or about one-fourth of the United States. The original forests covered not less than 850,000,000 acres.

Forests publicly owned contain one-fifth of all our standing timber. Forests privately owned contain four-fifths of the standing timber. The timber privately owned is not only four times that publicly owned, but is generally more valuable.

Forestry is now practiced on 70 per cent of the forests publicly owned and on less than 1 per cent of the forests privately owned, or on only 18 per cent of the total area of forests.

The yearly growth of wood in our forests does not average more than 12 cubic feet per acre. This gives a total yearly growth of less than 7,000,000,000 cubic feet.

We have 200,000,000 acres of mature forests, in which yearly growth is balanced by decay; 250,000,000 acres partly cut over or burned over, but restocking naturally with enough young growth to produce a merchantable crop, and 100,000,000 acres cut over and burned over, upon which young growth is lacking or too scanty to make merchantable timber.

We take from our forests yearly, including waste in logging and in manufacture, 23,000,000,000 cubic feet of wood. We use each year 100,000,000 cords of firewood; 40,000,000,000 feet of lumber; more than 1,000,000,000 posts, poles, and fence rails; 118,000,000 hewn ties; 1,500,000,000 staves; over 133,000,000 sets of heading; nearly 500,000,000 barrel hoops; 3,000,000 cords of native pulp wood; 165,000,000 cubic feet of round mine timbers, and 1,250,000 cords of wood for distillation.

Since 1870 forest fires have destroyed a yearly average of 50 lives and $50,000,000 worth of timber. Not less than 50,000,000 acres of forest is burned over yearly. The young growth destroyed by fire is worth far more than the merchantable timber burned.

One-fourth of the standing timber is lost in logging. The boxing of long-leaf pine for turpentine has destroyed one-fifth of the forests worked. The loss in the mill is from one-third to two-thirds of the timber sawed. The loss of mill product in seasoning and fitting for use is from one-seventh to one-fourth.

Of each 1,000 feet which stood in the forest, an average of only 320 feet of lumber is used.

We take from our forests each year, not counting the loss by fire, three and a half times their yearly growth. We take 40 cubic feet per acre for each 12 cubic feet grown; we take 260 cubic feet per capita, while Germany uses 37 and France 25 cubic feet.

We tax our forests under the general property tax, a method abandoned long ago by every other great nation. Present tax laws prevent reforestation of cut-over land and the perpetuation of existing forests by use.

Great damage is done to standing timber by injurious forest insects. Much of this damage can be prevented at small expense.

To protect our farms from wind and to reforest land best suited for forest growth will require tree planting on an area larger than Pennsylvania, Ohio, and West Virginia combined. Lands so far successfully planted make a total area smaller than Rhode Island; and year by year, through careless cutting and fires, we lower the capacity of existing forests to produce their like again, or else totally destroy them.

In spite of substitutes we shall always need much wood. So far our use of it has steadily increased. The condition of the world's supply of timber makes us already dependent upon what we produce. We send out of our country one and a half times as much timber as we bring in. Except for finishing woods, relatively small in amount, we must grow our own supply or go without. Until we pay for our lumber what it costs to grow it, as well as what it costs to log and saw, the price will continue to rise.

The preservation by use, under the methods of practical forestry, of all public forest lands, either in state or federal ownership, is essential to the permanent public welfare. In many forest States the acquirement of additional forest lands as state forests is necessary to the best interests of the States themselves.

The conservation of our mountain forests, as in the Appalachian system, is a national necessity. These forests are required to aid in the regulation of streams used for navigation and other purposes. The conservation of these forests is impracticable through private enterprise alone, by any State alone, or by the Federal Government alone. Effective and immediate cooperation between these three agencies is essential. Federal ownership of limited protective areas upon important watersheds, effective state fire patrol, and the cooperation of private forest owners are all required.

The true remedy for unwise tax laws lies not in laxity in their application nor in special exemptions, but in a change in the method of taxation. An annual tax upon the land itself, exclusive of the value of the timber, and a tax upon the timber when cut, is well adapted to actual conditions of forest investment, and is practicable and certain. It is far better that forest land should pay a moderate tax permanently than that it should pay an excessive revenue temporarily and then cease to pay at all.

Forests in private ownership can not be conserved unless they are protected from fire. We need good fire laws, well enforced. Fire control is impossible without an adequate force of men whose sole duty is fire patrol during the dangerous season.

The conservative use of the forest and of timber by American citizens will not be general until they learn how to practice forestry. Through a vigorous national campaign in education, forestry has taken root in the great body of American citizenship. The basis already exists upon which to build a structure of forest conservation which will endure. This needs the definite commitment of state governments and the Federal Government to their inherent duty of teaching the people how to care for their forests. The final responsibility, both for investigative work in forestry and for making its results known, rests upon the States and upon the nation.

By reasonable thrift, we can produce a constant timber supply beyond our present need, and with it conserve the usefulness of our streams for irrigation, water supply, navigation, and power.

Under right management our forests will yield over four times as much as now. We can reduce waste in the woods and in the mill at least one-third, with present as well as future profit. We can perpetuate the naval-stores industry. Preservative treatment will reduce by one-fifth the quantity of timber used in the water or in the ground. We can practically stop forest fires at a cost yearly of one-fifth the value of the merchantable timber burned.

We shall suffer for timber to meet our needs until our forests have had time to grow again. But if we act vigorously and at once we shall escape permanent timber scarcity.

WATERS.

The sole source of our fresh water is rainfall, including snow. From this source all running, standing, and ground waters are derived. The habitability of the country depends on these waters. Our mean annual rainfall is about 30 inches; the quantity about 215,000,000,000,000 cubic feet per year, equivalent to ten Mississippi rivers.

Of the total rainfall, over half is evaporated; about a third flows into the sea; the remaining sixth is either consumed or absorbed. These portions are sometimes called, respectively, the fly-off, the run-off, and the cut-off. They are partly interchangeable. About a third of the run-off, or a tenth of the entire rainfall, passes through the Mississippi. The run-off is increasing with deforestation and cultivation.

Of the 70,000,000,000,000 cubic feet annually flowing into the sea, less than 1 per cent is retained and utilized for municipal and community supply; less than 2 per cent (or some 10 per cent of that in the arid and semiarid regions) is used for irrigation; perhaps 5 per cent is used for navigation, and less than 5 per cent for power.

For municipal and community water supply there are protected catchment areas aggregating over 1,000,000 acres, and over $250,000,000 are invested in waterworks, with nearly as much more in the appurtenant catchment areas and other lands. The population so supplied approaches 10,000,000, and the annual consumption is about 37,500,000,000 cubic feet. The better managed systems protect the catchment areas by forests and grass; the water is controlled and the storm product used, but there is large waste after the water enters the mains.

For irrigation it is estimated that there are $200,000,000 invested in dams, ditches, reservoirs, and other works for the partial control of the waters, and that 1,500,000,000,000 cubic feet are annually diverted to irrigable lands, aggregating some 20,000 square miles. Except in some cases through forestry, few catchment areas are controlled, and few reservoirs are large enough to hold the storm waters. The waste in the public and private projects exceeds 60 per cent, while no more than 25 per cent of the water actually available for irrigation of the arid lands is restrained and diverted.

There are in continental United States 287 streams navigated for an aggregate of 26,226 miles, and as much more navigable if improved. There are also 45 canals, aggregating 2,189 miles, besides numerous abandoned canals. Except through forestry in recent years, together with a few reservoirs and canal locks and movable dams, there has been little effort to control headwaters or catchment areas in the interests of navigation, and none of our rivers are navigated to more than a small fraction even of their effective low-water capacity.

The water power now in use is 5,250,000 horsepower; the amount running over government dams and not used is about 1,400,000 horsepower; the amount reasonably available equals or exceeds the entire mechanical power now in use, or enough to operate every mill, drive every spindle, propel every train and boat, and light every city, town, and village in the country. While the utilization of water power ranks among our most recent and most rapid industrial developments, little effort has been made to control catchment areas or storm waters in any large way for power, though most plants effect local control through reservoirs and other works. Nearly all the freshet and flood water runs to waste, and the low waters which limit the efficiency of power plants are increasing in frequency and duration with the increasing flood run-off.

The practical utility of streams for both navigation and power is measured by the effective low-water stage. The volume carried when the streams rise above this stage is largely wasted and often does serious damage. The direct yearly damage by floods since 1900 has increased steadily from $45,000,000 to over $238,000,000. The indirect loss through depreciation of property is great, while a large loss arises in impeded traffic through navigation and terminal transfers.

The freshets are attended by destructive soil erosion. The soil matter annually carried into lower rivers and harbors or into the sea is computed at 783,000,000 tons. Soil wash reduces by 10 or 20 per cent the productivity of upland farms and increases channel cutting and bar building in the rivers. The annual loss to the farms alone is fully $500,000,000, and large losses follow the fouling of the waters and the diminished navigability of the streams.

Through imperfect control of the running waters lowlands are temporarily or permanently flooded. It is estimated that there are in mainland United States about 75,000,000 acres of overflow and swamp lands requiring drainage; that by systematic operation these can be drained at moderate expense, and that they would then be worth two or three times the present value and cost of drainage, and would furnish homes for 10,000,000 people.

It is estimated that the quantity of fresh water stored in lakes and ponds (including the American portion of the Great Lakes) is about 600,000,000,000,000 cubic feet, equivalent to three years' rainfall or eight years' run-off. Some 6,000,000 of our people draw their water supply from lakes.

A large part of that half of the annual rainfall not evaporated lodges temporarily in the soil and earth. It is estimated that the ground water to the depth of 100 feet averages 16⅔ per cent of the earth volume, or over 1,400,000,000,000,000 cubic feet, equivalent to seven years' rainfall or twenty years' run-off. This subsurface reservoir is the essential basis of agriculture and other industries and is the chief natural resource of the country. It sustains forests and all other crops and supplies the perennial springs and streams and wells used by four-fifths of our population and nearly all our domestic animals. Its quantity is diminished by the increased run-off due to deforestation and injudicious farming. Although the volume of the available ground water is subject to control by suitable treatment of the surface, little effort has been made to retain or increase it, and it is probable that fully 10 per cent of this rich resource has been wasted since settlement began. The water of the strata below 100 feet supplies artesian and deep wells, large springs, and thermal and mineral waters. It can be controlled only through the subsurface reservoir.

Of the 35,000,000,000,000 cubic feet of cut-off, the chief share is utilized by natural processes or by agriculture and related industries. On an average the plant tissue of annual growths is three-fourths and of perennial growths three-eighths water; of human and stock food over 80 per cent is water, and in animal tissue the ratio is about the same; and since water is the medium for organic circulation, the plants and animals of the country yearly require an amount many times exceeding their aggregate volume. Even in the more humid sections of the country the productivity of the soil and the possible human population would be materially increased by a greater rainfall, leaving a larger margin for organic and other chemical uses. Except through agriculture and forestry little general effort is made to control the annual cut-off, although some farmers in arid regions claim to double or triple the crop from given soil by supplying water just when needed and withholding it when not required.

Water is like other resources in that its quantity is limited. It differs from such mineral resources as coal and iron, which once used are gone forever, in that the supply is perpetual; and it differs from such resources as soils and forests, which are capable of renewal or improvement, in that it can not be augmented in quantity, though like all other resources it can be better utilized.

It is now recognized by statesmen and experts that navigation is interdependent with other uses of the streams; that each stream is essentially a unit from its source to the sea; and that the benefits of a comprehensive system of waterway improvement will extend to all the people in the several sections and States of the country.

It is also recognized, through the unanimous declaration of the governors of the States and Territories adopted in conference with the leading jurists and statesmen and experts of the country, that in the use of the natural resources the independent States are interdependent, and bound together by ties of mutual benefits, responsibilities, and duties.

It has recently been declared by a majority of our leading statesmen that it is an imperative duty to enter upon a systematic improvement, on a large and comprehensive plan, just to all portions of the country, of the waterways and harbors and Great Lakes, whose natural adaptability to the increasing traffic of the land is one of the greatest gifts of a benign Providence; while the minority indorsed the movement for control of the waterways still more specifically and in equally emphatic terms.

Within recent months it has been recognized and demanded by the people, through many thousand delegates from all States assembled in convention in different sections of the country, that the waterways should and must be improved promptly and effectively as a means of maintaining national prosperity.

The first requisite for waterway improvement is the control of the waters in such manner as to reduce floods and regulate the regimen of the navigable rivers. The second requisite is development of terminals and connections in such manner as to regulate commerce.

In considering the uses and benefits to be derived from the waters, the paramount use should be water supply; next should follow navigation in humid regions and irrigation in arid regions. The development of power on the navigable and source streams should be coordinated with the primary and secondary uses of the waters. Other things equal, the development of power should be encouraged, not only to reduce the drain on other resources, but because properly designed reservoirs and power plants retard the run-off and so aid in the control of the streams for navigation and other uses.

Broad plans should be adopted providing for a system of waterway improvement extending to all uses of the waters and benefits to be derived from their control, including the clarification of the water and abatement of floods for the benefit of navigation; the extension of irrigation; the development and application of power; the prevention of soil wash; the purification of streams for water supply; and the drainage and utilization of the waters of swamp and overflow lands.

To promote and perfect these plans scientific investigations, surveys, and measurements should be continued and extended, especially the more accurate determination of rainfall and evaporation, the investigation and measurement of ground water, the gauging of streams and determination of sediment, and topographic surveys of catchment areas and sites available for control of the waters for navigation and related purposes.

NATIONAL EFFICIENCY.

Since the greatest of our national assets is the health and vigor of the American people, our efficiency must depend on national vitality even more than on the resources of the minerals, lands, forests, and waters.

The average length of human life in different countries varies from less than twenty-five to more than fifty years. This span of life is increasing wherever sanitary science and preventive medicine are applied. It may be greatly extended.

Our annual mortality from tuberculosis is about 150,000. Stopping three-fourths of the loss of life from this cause, and from typhoid and other prevalent and preventable diseases, would increase our average length of life over fifteen years.

There are constantly about 3,000,000 persons seriously ill in the United States, of whom 500,000 are consumptives. More than half this illness is preventable.

If we count the value of each life lost at only $1,700 and reckon the average earning lost by illness as $700 per year for grown men, we find that the economic gain from mitigation of preventable disease in the United States would exceed $1,500,000,000 a year. In addition, we would decrease suffering and increase happiness and contentment among the people. This gain, or the lengthening and strengthening of life which it measures, can be secured through medical investigation and practice, school and factory hygiene, restriction of labor by women and children, the education of the people in both public and private hygiene, and through improving the efficiency of our health service—municipal, state, and national. The National Government has now several agencies exercising health functions which only need to be concentrated to become coordinated parts of a greater health service worthy of the nation.

The inventory of our natural resources made by your commission with the vigorous aid of all federal agencies concerned, of many States, and of a great number of associated and individual cooperators, furnishes a safe basis for general conclusions as to what we have, what we use and waste, and what may be the possible saving. But for none of the great resources of the farm, the mine, the forest, and the stream do we yet possess knowledge definite or wide enough to insure methods of use which will best conserve them.

In order to conserve a natural resource, we must know what that resource is by taking stock. We greatly need a more complete inventory of our natural resources; and this can not be made except through the active cooperation of the States with the nation.

The permanent welfare of the nation demands that its natural resources be conserved by proper use. To this end the States and the nation can do much by legislation and example. By far the greater part of these resources is in private hands. Private ownership of natural resources is a public trust; they should be administered in the interests of the people as a whole. The States and nation should lead rather than follow in the conservative and efficient use of property under their immediate control. But their first duty is to gather and distribute a knowledge of our natural resources and of the means necessary to insure their use and conservation, to impress the body of the people with the great importance of the duty, and to promote the cooperation of all. No agency, state, federal, corporate, or private, can do the work alone.

Finally, the conservation of our resources is an immediate and vital concern. Our welfare depends on conservation. The pressing need is for a general plan under which citizens, States, and nation may unite in an effort to achieve this great end. The lack of cooperation between the States themselves, between the States and the nation, and between the agencies of the National Government, is a potent cause of the neglect of conservation among the people. An organization through which all agencies—state, national, municipal, associate, and individual—may unite in a common effort to conserve the foundations of our prosperity is indispensable to the welfare and progress of the nation. To that end the immediate creation of a national agency is essential. Many States and associations of citizens have taken action by the appointment of permanent conservation commissions. It remains for the nation to do likewise, in order that the States and the nation, associations and individuals, may join in the accomplishment of this great purpose.

Accompanying this report, and transmitted as a part thereof, are detailed statements by the secretaries of the several sections, and many papers and illustrations prepared by experts at the request of your commission.

GIFFORD PINCHOT, *Chairman.*
W J MCGEE,
Secretary, Section of Waters.
OVERTON W. PRICE,
Secretary, Section of Forests.
GEORGE W. WOODRUFF,
Secretary, Section of Lands.
J. A. HOLMES,
Secretary, Section of Minerals.

Attest:
THOMAS R. SHIPP,
Secretary to the Commission.

DECEMBER 7, 1908.

JOINT CONSERVATION CONFERENCE

SUPPLEMENTARY REPORT

This joint conservation conference, in session assembled in the city of Washington on this 10th day of December, in the year 1908, representing the several States and Territories of the United States through governors of States, state conservation commissions, delegates, and representatives of state and national organizations dealing with natural resources, does hereby resolve and declare:

Having heard the report of the National Conservation Commission read, and having fully deliberated thereon, we hereby indorse the said report as a wise, just, and patriotic statement of the resources of the nation, of the thoughtless and profligate manner in which some of these resources have been and are being wasted, and of the urgent need for their conservation in the interests of this and future generations, to the end that the prosperity and perpetuity of the nation may be assured.

We especially approve of the principle of cooperation among the States and between these and the Federal Government laid down in that report and in the earlier report of the Inland Waterways Commission, and urge both state and federal legislatures to enact such laws as may be necessary to extend and apply such cooperation in all matters pertaining to the use and conservation of our resources.

We especially commend and urge the adoption of the policy of separate disposal of the surface rights, timber rights, and mineral rights on the remaining public lands of the United States; and we approve the disposal of mineral rights by lease only, and the disposal of timber rights only under conditions insuring proper cutting and logging with a view to the protection of growing timber and the watersheds and headwaters of streams used for navigation and other interstate purposes.

We also especially approve and indorse the proposition that all uses of the waters and all portions of each waterway should be treated as interrelated; and we emphatically urge prompt and effective legislation providing for the immediate and proper development of the waterways of the country for navigation, water supply, and other interstate uses, preferably by direct federal appropriations; otherwise by the issue of bonds.

Fully approving the policy of improving the waterways of the country for navigation and other interstate uses of the waters, we urge the prompt adoption of the broad plan recommended by the Inland Waterways Commission for waterway development under an executive board or commission appointed by and acting under the direction of the President of the United States.

Approving those portions of the report pointing out the need for continued investigation and more extended scientific research, we also urge that this policy of gaining more definite and specific knowledge relating to our resources be adopted by the several States no less than by the Federal Government.

Especially commending the portions of the report dealing with diminished national efficiency due to disease and premature death among our citizens, we urge the adoption of the policy of protecting life and health by States, municipalities, and communities, no less than by the Federal Government; and we urge further investigation of all other means whereby the efficiency of individual citizens, and hence of the State and nation may be increased.

We favor the maintenance of conservation commissions in every State, to the end that each Commonwealth may be aided and guided in making the best use of those abundant resources with which it has been blessed.

We also especially urge on the Congress of the United States the high desirability of maintaining a national commission on the conservation of the resources of the country, empowered to cooperate with state commissions, to the end that every sovereign Commonwealth and every section of the country may attain the high degree of prosperity and the sureness of perpetuity naturally arising in the abundant resources and the vigor, intelligence, and patriotism of our people.

Personnel of the Conference

The Joint Conservation Conference was composed of the following:

Hon. Wilford B. Hoggatt, governor of Alaska.
Hon. Joseph H. Kibbey, governor of Arizona.
Hon. X. O. Pindall, acting governor of Arkansas.
Hon. Rollin S. Woodruff, governor of Connecticut.
Hon. H. B. F. Macfarland, chairman Board of Commissioners, District of Columbia.
Hon. Preston Lea, governor of Delaware.
Hon. Napoleon B. Broward, governor of Florida.
Hon. Hoke Smith, governor of Georgia.
Hon. W. F. Frear, governor of Hawaii.
Hon. Charles S. Deneen, governor of Illinois.
Hon. Walter R. Stubbs, governor-elect of Kansas.
Hon. Jared T. Sanders, governor of Louisiana.
Hon. Austin L. Crothers, governor of Maryland.
Hon. Curtis Guild, jr., governor of Massachusetts.
Hon. Fred M. Warner, governor of Michigan.
Hon. John A. Johnson, governor of Minnesota.
Hon. E. F. Noel, governor of Mississippi.
Hon. George Curry, governor of New Mexico.
Hon. John Burke, governor of North Dakota.
Hon. George E. Chamberlain, governor of Oregon.
Hon. Régis H. Post, governor of Porto Rico.
Hon. Martin F. Ansel, governor of South Carolina.
Senator William C. Edwards, representative of Canada.
Hon. R. H. Campbell, representative of Canada.
Mr. Andrew Carnegie.
Mr. John Mitchell.
Dr. Albert Shaw, editor Review of Reviews.
Personal representatives of governors:
    Mr. J. C. Needham, California.
    Mr. William G. Evans, Colorado.
    Hon. Eugene Hale, Maine.
    Col. John A. Ockerson, Missouri.
    Hon. Francis G. Newlands, Nevada.

Personal representatives of governors—Continued.

- Mr. Philip W. Ayres, New Hampshire.
- Hon. James S. Whipple, New York.
- Hon. Rosewell Page, Virginia.
- Hon. William Irvine, Wisconsin.
- Hon. Charles R. Van Hise, Wisconsin.
- Hon. William E. Mullen, Wyoming.

Representatives of the States:

- **Alabama—**
  - Hon. W. P. Lay, chairman conservation commission.
  - Hon. Frank H. Lathrop, member conservation commission.
  - Mr. J. B. Powell, member conservation commission.
- **California—**
  - Mr. Francis Cuttle, member conservation commission.
  - Mr. Frank H. Short, member conservation commission.
  - Mrs. Lovell White, member conservation commission.
  - Mr. Grant Conard.
- **Colorado—**
  - Hon. Simon Guggenheim, U. S. Senator from Colorado.
  - Mr. I. N. Stevens, member conservation commission.
  - Mr. Clarence P. Dodge, member conservation commission.
  - Mr. Ellsworth Bethel, member conservation commission.
  - Mr. Brooks Irlone.
- **Connecticut—**
  - Mr. Albert N. Abbee.
  - Mr. R. T. Crane.
- **Delaware—**
  - Hon. Benjamin Nields, member conservation commission.
- **Florida—**
  - Hon. William H. Milton, U. S. Senator from Florida, and chairman conservation commission.
  - Hon. Duncan U. Fletcher, member conservation commission.
- **Georgia—**
  - Mr. John A. Betjiman, member conservation commission.
- **Illinois—**
  - Hon. Isham Randolph, chairman conservation commission.
  - Dr. H. Foster Bain, member conservation commission.
  - Dr. Cyril C. Hopkins, member conservation commission.
  - Mr. Glenn W. Traer, member conservation commission.
- **Indiana—**
  - Hon. Henry Riesenberg, chairman conservation commission.
  - Hon. Chas. S. Bash, member conservation commission.
  - Mr. Joseph D. Oliver, member conservation commission.
  - Mr. E. W. Wickey, member conservation commission.
- **Kentucky—**
  - Mr. John B. Atkinson, member proposed conservation commission.
  - Mr. Wm. R. Belknap, member proposed conservation commission.
  - Hon. D. C. Edwards, member proposed conservation commission.
  - Mr. Fred W. Keisker, member proposed conservation commission.
  - Mr. F. C. Nunemacher, member proposed conservation commission.
  - Mr. J. C. Tomlin, member proposed conservation commission.
  - Mr. J. B. Bennett.
  - Gen. John B. Castleman.
  - Mr. A. D. James.
  - Mr. John W. Langley.
  - Col. A. T. McDonald.
  - Mr. Clifton J. Waddill.
- **Louisiana—**
  - Hon. Henry E. Hardtner, chairman conservation commission.
  - Hon. Harry P. Gamble, secretary conservation commission.
  - Maj. F. M. Kerr, member conservation commission.
- **Maryland—**
  - Mr. Bernard N. Baker, chairman conservation commission.
  - Prof. William Bullock Clark, member conservation commission.
  - Mr. Edward Hirsch, member conservation commission.
- **Massachusetts—**
  - Prof. Frank W. Rane, chairman conservation commission.

Representatives of the States—Continued.

Michigan—
- Hon. Wm. H. Rose, chairman forestry commission.
- Hon. W. B. Mershon, member forestry commission.
- Hon. Wm. F. Knox.
- Hon. Huntley Russell, commissioner of the state land office.

Minnesota—
- Hon. F. B. Lynch.
- Mr. P. H. Nelson.
- Mr. S. D. Works.

Mississippi—
- Prof. H. L. Whitfield.

Missouri—
- Mr. W. K. Kavanaugh, chairman commission on waterways.
- Dr. Herman Von Schrenk, chairman commission on forestry.
- Dr. William H. Black, member commission on waterways.
- Mr. T. H. Herring, member commission on waterways.
- Mr. W. K. James, member commission on waterways.
- Mr. S. Waters Fox.

Nebraska—
- Prof. G. E. Condra, chairman conservation commission.
- Mr. P. H. Marlay, member conservation commission.
- Mr. F. D. Wead, member conservation commission.

New Jersey—
- Mr. E. B. Voorhees, chairman conservation commission.
- Mr. Alfred Gaskill, state forester and member conservation commission.
- Dr. Henry B. Kümmel, member conservation commission.
- Mr. Henry J. Sherman, member conservation commission.
- Mr. Morris R. Sherrerd, member conservation commission.

New Mexico—
- Hon. Solomon Luna, chairman conservation commission.
- Hon. H. W. Kelly, member conservation commission.

New York—
- Hon. Raymond A. Pearson, member conservation commission.
- Hon. Henry H. Persons, member conservation commission.
- Hon. Frederick Skene, member conservation commission.
- Hon. Frederick C. Stevens, member conservation commission.

Ohio—
- Mr. Jacob A. Beidler, chairman forestry bureau.

Oregon—
- Hon. Joseph N. Teal, chairman conservation commission.

Pennsylvania—
- Dr. J. T. Rothrock, chairman conservation commission.
- Mr. Powell Evans, member conservation commission.
- Mr. A. B. Farquhar, member conservation commission.
- Col. Wm. S. Harvey, member conservation commission.
- Hon. W. R. Smith, Member of Congress.

Rhode Island—
- Mr. Henry A. Barker, chairman conservation commission.
- Mr. J. Herbert Shedd, member conservation commission.
- Mr. Jesse B. Mowry.

South Carolina—
- Mr. E. J. Watson, chairman conservation committee.
- Prof. Earle Sloan, member conservation committee.

South Dakota—
- Hon. Robert J. Gamble, chairman conservation commission.
- Mr. Eben W. Martin, member conservation commission.

Tennessee—
- Prof. L. C. Glenn.

Utah—
- Hon. O. J. Salisbury, chairman conservation commission.
- Hon. A. W. Ivins, member conservation commission.

Virginia—
- Hon. P. St. Julian Wilson, chairman conservation commission.
- Dr. Thomas L. Watson, member conservation commission.
- Hon. George W. Koiner, member conservation commission.
- Hon. W. E. Bibb, member conservation commission.

Representatives of the States—Continued.

West Virginia—
- Mr. Hu Maxwell, chairman conservation commission.
- Mr. Neil Robinson, member conservation commission.
- Mr. James H. Stewart, member conservation commission.
- Mr. G. W. Atkinson.

Representatives of national organizations:

American Academy of Political and Social Science—
- Prof. Emory R. Johnson, chairman conservation committee.
- Dr. S. M. Lindsay, member conservation committee.

American Association for the Advancement of Science—
- Prof. Wm. F. M. Goss, personal representative of the president.

American Association of Agricultural Colleges and Experiment Stations—
- Mr. J. L. Snyder, president.

American Automobile Association—
- Mr. Powell Evans, personal representative.
- Mr. C. Gordon Neff, member conservation committee.

American Bar Association—
- Mr. John Hinckley, secretary.

American Chemical Society—
- Prof. Marston T. Bogert, president.
- Dr. F. W. Clarke, chief chemist U. S. Geological Survey, and member conservation committee.
- Mr. R. B. Dole, member conservation committee.

American Civic Association—
- Mr. J. Horace McFarland, president.
- Mr. Clinton Rogers Woodruff, secretary.
- Mr. A. B. Farquhar, member conservation committee.

American Electrochemical Society—
- Mr. Edward G. Acheson, president.
- Mr. Edward R. Taylor, chairman conservation committee.

American Federation of Labor—
- Mr. Samuel Gompers, president.
- Mr. James O'Connell, third vice-president.
- Mr. Frank Morrison, secretary.

American Forestry Association—
- Col. Wm. S. Harvey, member board of directors.

American Institute of Architects—
- Mr. Cass Gilbert, president.

American Institute of Electrical Engineers—
- Mr. John H. Finney, member conservation committee.

American Institute of Mining Engineers—
- Mr. John Hays Hammond, president.

American Medical Association—
- Dr. Herbert L. Burrell, president.
- Dr. J. H. Musser, chairman conservation committee.
- Dr. George W. Gay, member conservation committee.

American Mining Congress—
- Judge J. H. Richards, president.
- Mr. E. R. Buckley, first vice-president.
- Mr. J. T. Callbreath, jr., secretary.

American Newspaper Publishers Association—
- Mr. John Norris, chairman conservation committee.

American Railway Association—
- Mr. Arthur Hale, personal representative.

American Railway Engineering and Maintenance of Way Association—
- Mr. Wm. McNab, president.

American Scenic and Historic Preservation Society—
- Mr. Hiram J. Messenger.

American Society of Civil Engineers—
- Mr. Chas. Macdonald, president.

Representatives of national organizations—Continued.

- American Society of Mechanical Engineers—
  - Mr. Calvin W. Rice, secretary.
  - Mr. Luther D. Burlingame, representative conservation committee.
  - Mr. John R. Freeman, member advisory board.
  - Mr. Jesse M. Smith.
- American Society for Testing Materials—
  - Mr. Chas. B. Dudley, president.
- Appalachian National Forest Association—
  - Hon. D. A. Tompkins, president.
  - Mr. John H. Finney, secretary.
- Atlantic Deeper Waterways Association—
  - Hon. J. Hampton Moore, president.
- Business Men's League of America—
  - Mr. James E. Smith, president.
  - Mr. Wm. F. Saunders, secretary.
  - Mr. Clarence H. Howard, member conservation committee.
  - Mr. Geo. W. Simmons, member conservation committee.
- Carriage Builders' National Association—
  - Mr. Geo. H. Babcock, member conservation committee.
  - Mr. W. P. Champney, member conservation committee.
- Conservation League of America—
  - Mr. Walter L. Fisher, president.
  - Mr. John F. Bass.
  - Mr. Lauriston Ward.
- Farmers' National Congress—
  - Hon. B. Cameron, president.
  - Mr. A. C. Fuller, member executive committee.
  - Mr. E. W. Wickey, member executive committee.
- General Federation of Women's Clubs—
  - Mrs. F. W. Gerard, chairman committee on forestry.
  - Mrs. John D. Wilkinson, chairman committee on waterways.
  - Miss Laura D. Gill.
- International Tax Association—
  - Mr. Lawson Purdy, vice-president.
  - Mr. A. C. Pleydell, secretary.
- Interstate Inland Waterway—
  - Mr. C. S. E. Holland, president.
- Interstate Mississippi River Improvement Association—
  - Mr. Charles Scott, president.
- Lakes-to-the-Gulf-Deep Waterway Association—
  - Mr. Wm. K. Kavanaugh, president.
  - Mr. Wm. F. Saunders, secretary.
  - Mr. Lyman E. Cooley, member conservation committee.
  - Hon. X. O. Pindall, member conservation committee.
  - Mr. Charles Scott, member conservation committee.
  - Mr. James E. Smith, member conservation committee.
- Missouri River Improvement Association—
  - Col. Henry T. Clarke, president.
- National Academy of Sciences—
  - Dr. Ira Remsen, president.
  - Prof. William Bullock Clark, chairman conservation committee.
  - Prof. E. G. Conklin, member conservation committee.
- National Association of Agricultural Implements and Vehicle Manufacturers—
  - Mr. Newell Sanders, chairman conservation committee.
- National Association of Audubon Societies—
  - Mr. T. Gilbert Pearson, member conservation committee.
- National Association of Cotton Manufacturers—
  - Mr. C. J. Woodbury, secretary.
- National Association of Manufacturers—
  - Mr. James W. Van Cleave, president.
- National Board of Fire Underwriters—
  - Mr. J. Montgomery Hare, president.

Representatives of national organizations—Continued.

- National Board of Trade—
  - Mr. Frank D. La Lanne, president.
- National Business League of America—
  - Mr. La Verne W. Noyes, president and member conservation commission.
  - Mr. Victor Falkenau, chairman conservation commission.
  - Mr. A. B. Farquhar, member conservation commission.
- National Civic Federation—
  - Mr. John Mitchell, chairman trade agreement department.
- National Council of Commerce—
  - Mr. George L. McCarthy, member conservation committee.
  - Mr. H. E. Miles, member conservation committee.
  - Mr. Frank B. Wiborg, member conservation committee.
- National Drainage Association—
  - Hon. Napoleon B. Broward, president.
- National Editorial Association—
  - Mr. Chester Harrison, member conservation committee.
- National Electric Light Association—
  - Mr. Dudley Farrand, chairman conservation committee.
- National Forest Conservation League—
  - Hon. Samuel R. Van Sant, president.
  - Mr. Theodore Knappen, secretary.
  - Mr. W. S. Dwinnell.
- National Grange—
  - Mr. H. J. Patterson.
- National Hay Association—
  - Mr. Maurice Neizer, president.
- National Hickory Association—
  - Mr. H. D. Hartley, secretary and member conservation committee.
- National Irrigation Congress—
  - Mr. George E. Barstow, president.
- National Lumber Manufacturers' Association—
  - Mr. George K. Smith, secretary.
- National Municipal League—
  - Mr. Clinton Rogers Woodruff, secretary.
- National Slack Cooperage Manufacturers' Association—
  - Mr. C. M. Van Aiken, president.
- National Tax Association—
  - Mr. A. C. Pleydell.
  - Mr. Lawson Purdy.
- Trans-Mississippi Commercial Congress—
  - Mr. Thomas F. Walsh, president.
  - Mr. J. T. Callbreath, jr.
  - Mr. J. B. Case.
  - Mr. F. W. Fleming.
  - Mr. I. T. Pryor.
- Upper Mississippi River Improvement Association—
  - Mr. Thomas Wilkinson, president.
- Woman's National Rivers and Harbors Congress—
  - Mrs. Frances Shuttleworth, corresponding secretary.

Bureau chiefs and experts:

- Geological Survey—
  - Dr. George Otis Smith, Director.
  - Mr. Henry Gannett, geographer national conservation commission.
  - Mr. Robert Follansbee.
  - Mr. R. B. Dole.
  - Dr. D. T. Day.
  - Mr. M. R. Campbell.
  - Dr. C. W. Hayes.
  - Mr. M. O. Leighton.

Bureau chiefs and experts—Continued.

Geological Survey—Continued.
- Mr. W. C. Mendenhall.
- Mr. E. W. Parker.
- Mr. F. B. Van Horn.
- Dr. Bailey Willis.
- Mr. H. M. Wilson.

Forest Service—
- Mr. Wm. T. Cox.
- Mr. Wm. L. Hall.
- Mr. R. S. Kellogg.
- Mr. A. C. Shaw.
- Mr. Philip P. Wells.
- Mr. E. A. Ziegler.

General Land Office—
- Hon. Fred Dennett, Commissioner.
- Mr. Francis W. Clements, first assistant attorney.
- Mr. E. C. Finney.

Bureau of Statistics, Department of Commerce and Labor—
- Dr. O. P. Austin, Chief.

Bureau of Entomology—
- Dr. L. O. Howard, Chief.
- Mr. C. L. Marlatt.
- Dr. A. D. Hopkins.

Weather Bureau—
- Prof. Willis L. Moore, Chief.
- Prof. Harry C. Frankenfield.

Reclamation Service—
- Mr. Morris Bien.

Indian Office—
- Mr R. G. Valentine.

Bureau of Plant Industry—
- Dr. B. T. Galloway, Chief.

Bureau of Corporations—
- Mr. W. B. Hunter.

Biological Survey—
- Dr. C. Hart Merriam, Chief.

Bureau of Statistics, Department of Agriculture—
- Hon. Victor H. Olmsted, Chief Statistician.

Bureau of Fisheries—
- Mr. Hugh M. Smith.

Office of Experiment Stations—
- Dr. A. C. True, Director.

Bureau of Chemistry—
- Dr. H. W. Wiley, Chief.

Bureau of Soils—
- Dr. Milton Whitney, Chief.

Delegates at Large:
- Mr. Victor C. Alderson, Colorado.
- Mr. Geo. N. Babb, New York.
- Mr. R. Dan Benson, Pennsylvania.
- Mr. Chas. W. Bernhardt, Georgia.
- Mr. Nathan D. Bill, Massachusetts.
- Mr. George Black, Washington.
- Mr. W. F. Black, Alabama.
- Mr. L. W. Brown, Virginia.
- Mr. W. P. Brown, Washington.
- Mr. A. W. Butler, Maine.
- Mr. Joseph L. Cahall, Delaware.
- Mr. W. M. Cameron, Tennessee.
- Mr. Thomas W. Carmichael.
- Mr. S. H. Chappell, Georgia.
- Mr. R. F. Clerc, Louisiana.

Delegates at large—Continued.

Mr. Geo. Ward Cook, Massachusetts.
Mr. S. A. Cosulich, Louisiana.
Mr. S. H. Cowan, Texas.
Mr. John Craft, Alabama.
Mr. Thomas F. Cunningham, Louisiana.
Mr. A. W. Damon, Massachusetts.
Mr. J. A. Delfeker, Wyoming.
Mr. Gould Dietz, Omaha.
Mr. Theodore Dwight, New York.
Mr. C. H. Ellis, Louisiana.
Mr. B. F. Eshleman, Wyoming.
Mr. John W. Faxon, Tennessee.
Mr. Chas. D. Gates, Kentucky.
Dr. Edward Everett Hale, Washington, D. C.
Mr. Henry R. Hayes, Massachusetts.
Mr. W. S. Holman, Texas.
Mr. E. S. Johnson, Georgia.
Mr. P. G. Johnston, Idaho.
Mr. Charles P. Johnston, Louisiana.
Mr. H. S. Keathoper, Alabama.
Mr. M. N. Kline, Pennsylvania.
Mr. Victor M. Lefebere, Louisiana.
Mr. Sidney F. Lewis, Louisiana.
Mr. H. H. Little, Virginia.
Mr. Wm. McCarroll, New York.
Mr. J. T. McClellan.
Mr. V. Manvin, Louisiana.
Mr. Josiah Marvel, Delaware.
Mr. H. J. Messenger, Connecticut.
Mr. Roy Miller, Texas.
Mr. R. A. Mitchell, Alabama.
Mr. S. F. Mosle, Texas.
Mr. W. J. Nebb, Georgia.
Mrs. Mary M. North, Maryland.
Mrs. Lina Simpson Poffenboyer, West Virginia.
Mr. Wm. F. Prouty, Alabama.
Mr. J. T. Pryor, Texas.
Mr. C. E. Rafferty, Washington, D. C.
Hon. F. A. Richards, Massachusetts.
Mr. Franklin C. Robinson, Maine.
Mr. G. A. Rogers, Kansas.
Mr. W. B. Royster, Tennessee.
Mr. F. D. Ryan, Washington.
Mr. C. G. Smith, New York.
Mr. H. C. Smith, Louisiana.
Mr. Edwin A. Start, Massachusetts.
Mr. Charles J. Swift, Georgia.
Mr. E. C. Taleny, Mississippi.
Mr. S. Taliaferrio, Texas.
Mr. M. B. Trezevant, Louisiana.
Mr. Louis Ed. Vanoft, Louisiana.
Mr. J. S. Warren, Tennessee.
Mr. J. H. Woods, Massachusetts.

WATER RESOURCES.

WHAT WE HAVE.

The sole source of our fresh water is rainfall (including snow). From this source our running, standing, and ground waters are derived. The habitability of the country depends on these waters.

Through the observations and measurements of the Weather Bureau at some 4,000 stations our rainfall is known more accurately than that of any other equal area on the globe. The records furnished by Chief Willis L. Moore, interpreted and reduced by Henry Gannett, show a yearly mean of approximately 30 inches. The quantity falling on the land averages about 200,000,000,000,000 cubic feet per year; including the rainfall on water areas, it is 215,000,000,000,000 cubic feet.[a] The volume is ten Mississippi rivers.

The yearly rainfall on the more humid two-fifths of the country east of the ninety-fifth meridian (or what may be called the State Divide forming the eastern boundary of the Median States—North Dakota, South Dakota, Nebraska, Kansas, Oklahoma, and Texas) is nearly 48 inches; the quantity about 140,000,000,000,000 cubic feet. On the semiarid fifth of our area in these Median States (or between the ninety-fifth and one hundred and third meridians) the rainfall averages 30 inches and aggregates over 40,000,000,000,000 cubic feet. The rainfall on the western two-fifths of the country, including our arid lands, averages about 12 inches, or some 35,000,000,000,000 cubic feet.

---

[a] The quantitative view of water, except in smaller measures, is so new to thought that familiar units are lacking. Municipal water supply is generally expressed in gallons, irrigation water in acre-feet, stream flow in second-feet (or more accurately seconds-feet), and water for certain uses in the variable and indefinite miner's inch. There is urgent need of a unit applicable to the quantities commonly used for water supply, irrigation, and various other purposes. Moderate familiarity with the metric system would render convenient as such a unit the stere (equivalent to the kiloliter or cubic meter, the virtual basis of the metric system for capacity or tridimensional measure), which roughly approximates—like the liter the quart—the cubic yard in quantity and the ton in weight of water, while the kilostere approximates 1,000 tons and an acre-foot. The kilostere is especially convenient in discussing the water supply of the United States in that it permits expression of the leading values in round numbers not too large for ready comprehension—the mean rainfall totaling 6,000,000,000 kilosteres, and its main derivative fractions being expressible in sixths of this total. A kilostere of water is equivalent to a cube of 32.8 feet.

A few of the equivalents involved in the use of the stere for the measurement of water (reckoned at maximum density) follow:

1 liter=1.057 quarts; 0.264 gallon; 61.023 cubic inches; 2.205 pounds.
1 kiloliter=1,000 liters; 1 stere; 1 cubic meter; 264.17 gallons; 35.314 cubic feet; 2,204.62 pounds.
1 kilostere=1,000 kiloliters; 264,180 gallons; 35,314.45 cubic feet; 0.8107 acre-foot; 1,102.31 tons.
1 gallon=3.785 liters; 231 cubic inches; 0.1336 cubic foot; 8.34 pounds.
1 cubic foot=28.317 liters; 7.48 gallons; 62.43 pounds.
1 cubic mile=147,197,952,000 cubic feet; 4,168.208 kilosteres; 3,397,200 acre-feet; 4,594,784,072 tons.
1 ton=2,000 pounds; 32.04 cubic feet; 907.19 liters; 239.65 gallons.
1 pound=27.68 cubic inches; 0.4536 liter; 0.12 gallon.
215,000,000,000,000 cubic feet=6,088,236,690 kilosteres; 4,935,720,845 acre-feet; 1,460.6 cubic miles.
215,000,000,000,000 cubic feet±6,000,000,000 kilosteres; 5,000,000,000 acre-feet; 1,500 cubic miles.

Of the total rainfall, over half is evaporated; about a third flows into the sea; the remaining sixth is either consumed or absorbed. These portions, which may be called, respectively, the fly-off, the run-off, and the cut-off, are partly interchangeable. About a third of the run-off, or a tenth of the entire rainfall, passes through the Mississippi. The run-off is increasing with cultivation and deforestation.

The 110,000,000,000,000 cubic feet of fly-off influences climate, and thus affects agriculture and other industries. Except in moderate degree through management of the land surface, it is beyond artificial control.

The 70,000,000,000,000 cubic feet of run-off is available for water supply, irrigation, navigation, and power. It is controlled in small part, and may be wholly controlled by proper means.

The remainder of the rainfall (or cut-off) is either consumed in plant growth and other chemical combinations, or else permeates the deeper strata and passes subterraneously into the sea. It is partly controlled, chiefly through farming and forestry; and the control may be much increased.

WHAT WE USE AND WASTE.

Of the 110,000,000,000,000 cubic feet of water annually evaporated, a reasonable use is made through the settlement and general industrial development of the country. It is adapted to largely increased population and industries.

Of the 70,000,000,000,000 cubic feet annually flowing into the sea, little more than 100,000,000,000 cubic feet, or one-seventh of 1 per cent, is taken from rivers and lakes and protected catchment areas for municipal and community supply and related purposes; less than 2 per cent (or some 10 per cent of that in the arid and semiarid regions) is used for irrigation; perhaps 5 per cent may be reckoned as in small use for navigation; and less than 5 per cent is utilized for power. It is estimated that 85 per cent to 95 per cent of the volume is wasted in freshets or destructive floods.

It is reckoned by Chief Leighton of the hydrographic branch of the Geological Survey that for municipal and community water supply there are protected catchment areas aggregating over 1,000,000 acres, and that fully $250,000,000 are invested in waterworks with nearly as much more in the appurtenant catchment areas and other lands. The population so supplied approaches 10,000,000; the annual consumption is about 37,500,000,000 cubic feet, or one-twentieth of 1 per cent of our run-off. The better managed systems protect the catchment areas by forests or grass; the water is completely controlled, the storm product is stored, and there is little waste save through overlavish use after the impounded flow enters the mains.

For irrigation it is estimated by Director Newell of the Reclamation Service that there are $200,000,000 in vested in dams, ditches, reservoirs, and other works for the partial control of the waters (in addition to the value of the land, which is virtually fixed by the availability of the water); and that 1,500,000,000,000 cubic feet, i. e., three-quarters of 1 per cent of our total rainfall, or 2 per cent of that on the western two-fifths of our area, are annually diverted to irrigable lands aggregating some 13,000,000 acres. Except in some cases through forestry, there is little effort to control the catchment areas, and few reservoirs are large enough to hold the storm waters; so that the waste in public and private projects exceeds 60 per cent, while less than 25 per cent of the water actually available for irrigation of the arid lands is restrained and diverted.

There are in mainland United States 287 streams navigated for an aggregate of 26,226 miles,[a] and about an equal additional mileage might be made navigable by waterway improvements. There are also 45 canals with a mileage of 2,189, besides numerous abandoned canals.[b] On lake and sound routes there is large traffic, but the navigation of rivers and canals is too small for definite record. Several hundred million dollars have been expended on special projects, yet, "in spite of large appropriations for their improvement, our rivers are less serviceable for interstate commerce to-day than they were half a century ago."[c] The cost of water carriage averaging about one-fourth that of rail carriage, and our railway freightage during 1906 reaching 217,000,000,000 ton-miles at an average rate of 0.77 cent, the shipping of one-fifth of our freight by water would have saved over $250,000,000 to our producers and consumers. Except through forestry in recent years, together with a few reservoirs and canal locks and movable dams, there has been little effort to control headwaters or catchment areas in the interests of navigation; and none of our rivers are navigated to more than a small fraction even of their effective low-water capacity.

The theoretical power of the streams is reckoned by Leighton at 230,000,000 horsepower. The amount now in use is computed by the Census Office at 5,350,000 horsepower, and the amount running over government dams and not used is estimated by the Chief of Engineers at about 1,400,000 horsepower. The amount now available at a cost comparable with that of steam installation is estimated by the hydrographic branch of the Geological Survey at 37,000,000 horsepower, and the amount prospectively available at 75,000,000 to 150,000,000 horsepower. The 37,000,000 horsepower to-day available exceeds our entire mechanical power now in use, and would operate every mill, drive every spindle, propel every train and boat, and light every city, town, and village in the country. The nominal value is $20 per horsepower year; the price ranges up to $100 or $150. While the utilization of water power ranks among our most recent and most rapid industrial developments, little effort has been made to control catchment areas or storm waters in any large way for power development, though most plants effect local control through reservoirs and structures. Nearly all of the freshet and flood water runs to waste, and the low waters which limit the efficiency of power plants are increasing in frequency and duration with the increasing flood run-off.

---

[a] Preliminary Report of the Inland Waterways Commission, 1908: Herbert Knox Smith on "Navigable Streams of the United States," p. 35.

[b] Ibid.: Herbert Knox Smith on "Canals in the United States," p. 192.

[c] Ibid.: "Message of the President," p. vi.

The practical utility of streams for both navigation and power is measured by the effective low-water stage; the volume carried when the streams rise above this stage (75 to 90 per cent of the run-off) is not only wasted but does serious damage. The direct yearly damage by floods since 1900, as computed by Leighton, has increased steadily from $45,000,000 to more than $238,000,000; the indirect loss through depreciation of property is probably greater; while the largest loss is that arising in impeded traffic through navigation and terminal transfers.

The freshets are attended by destructive soil erosion. The soil matter annually carried into lower rivers and harbors or into the sea has recently been reckoned by Dole and Stabler at 783,000,000 tons. Its removal seriously reduces the productivity of upland farms, and increases channel cutting and bar building in the rivers. It is estimated that soil erosion reduces farm production 10 to 20 per cent; that the annual loss to the farms alone is $500,000,000; and that large losses follow the fouling of the waters and the diminished navigability of the streams.

Through imperfect control of the running waters, lowlands are temporarily or permanently flooded. It is estimated that there are in mainland United States 75,000,000 to 80,000,000 acres of overflow and swamp lands requiring drainage; that by systematic operations these might be drained and the water made available at moderate expense, and that they would then be worth two or three times the present value and cost of drainage, and would furnish homes for 10,000,000 inhabitants.

A part of the run-off lodges temporarily in lakes and ponds. It is estimated that the quantity of fresh water so stored (including the American portion of the Great Lakes) is about 600,000,000,000,000 cubic feet, equivalent to three years' rainfall or nine years' run-off. Over the water surface evaporation is rapid, and the influence of the lakes on climate is correspondingly large; and the natural reservoirs yield a water supply ordinarily requiring no control of catchment area. Some 6,000,000 of our people draw their water supply from lakes. All the larger and deeper lakes are navigated; they serve the chief part of our inland commerce by water.

A large part of that half of the annual rainfall not evaporated lodges temporarily in the soil and earth as ground water. According to texture, fire-dry rocks contain 1 to 3 per cent, air-dry rocks 5 to 25 per cent, and saturated rocks and earths 10 to 40 per cent of water, while the optimum moisture for plant growth in top soil ranges from 4 to 20 per cent; and it is estimated that the ground water to the depth of 100 feet (in which it is available for hand pumps and capillarity and deep-rooted trees) averages 5 per cent over 1,000,000 square miles, 20 per cent over another third of the country, and 25 per cent over the remaining third, a mean of 16⅔ per cent. This ground water forms a subsurface reservoir of over 1,400,000,000,000,000 cubic feet, equivalent to seven years' rainfall or twenty years' run-off. It is the essential basis of agriculture and most other industries, and the chief natural resource of the country; it sustains forests and all other crops, and supplies the perennial streams and springs and wells used by four-fifths of our population and nearly all our domestic animals. Its quantity is diminished by the increased run-off due to deforestation and injudicious farming. Throughout the upland portions of eastern United States the average water table has been lowered 10 to 40 feet, so that fully three-fourths of the springs and shallower wells have failed and many brooks have run dry, while the risk of crop loss by drought has proportionately increased. Although the available ground water is subject to control by such treatment of soil and plant growth as to prevent freshets, little effort has been made to retain it or increase its volume, and it is probable that fully 10 per cent of this rich resource has been allowed to drain away since settlement began. The water of the deeper rocks (below 100 feet) supplies artesian and other deep wells, thermal and mineral waters, and large springs. It can be controlled in part, chiefly through the subsurface reservoir, and the supply may be much better utilized.

Of the 35,000,000,000,000 cubic feet of cut-off, the chief share is utilized in natural processes or by agriculture and related industries. On an average, plant tissue in annual growths is three-fourths and in perennial growths three-eighths water; of human and stock food over 80 per cent is water, and in animal tissue the ratio is about the same; and water is the chief vehicle for the transmission of enteric and many other diseases. Since water is the medium for organic circulation, the plants and animals of the country yearly require an amount many times exceeding their aggregate volume. The average man of 150 pounds ingests over a ton (32 cubic feet, or 13 times his volume) of water each year, and an average bushel of corn requires over 700 cubic feet, or 22 tons, of water in the making, of which the larger part is evaporated and added to the fly-off. Even in the more humid sections of the country the productivity of the soil and the possible human population would be much larger if the rainfall were greater, leaving a wider margin for organic and other chemical uses. Except through agriculture and forestry, little general effort is made to control the annual cut-off, although some farmers in arid regions claim to double or triple the crop from given soil by supplying water just when needed and withholding it when not required.

WHERE WE STAND.

Our stock of water is like other resources in that its quantity is limited. It differs from such mineral resources as coal and iron, which once used, are gone forever, in that the supply is perpetual; and it differs from such resources as soils and forests, which are capable of renewal or increase (provided the supply of water suffices), in that its quantity can not be augmented. It differs also in that its relative quantity is too small to permit full development of other resources and of the population and industries depending on them. Like all other resources, it may be better utilized. It must be better utilized in order to derive full benefit from lands and forests and mines.

Although our rainfall of 215,000,000,000,000 cubic feet is 2,500,000 cubic feet per capita for a population of 86,000,000 (or 250,000 cubic feet, allowing for the 90 per cent waste), our growth in population and industries is seriously retarded by dearth and misuse of water. Fully a third of our territory (1,000,000 square miles, the area of Great Britain, Germany, France, Spain, Portugal, Italy, Austria, and Denmark combined) remains practically unoccupied and nearly unproductive by reason of aridity; while the public lands sufficiently humid for agricultural settlement are taken, the cost of transportation is limiting production, and our citizens are emigrating in thousands to other countries. With half our land area and the same water, our capacity for population and industries would be great as now; with twice our water equably distributed over our present land, our capacity would be more than doubled.

Hitherto water has seldom been regarded as a resource to be exploited and conserved; it has been viewed vaguely as a prime necessity, yet merely as a natural incident or providential blessing. In its assumed plenitude the idea of quantity has seldom arisen, though the waste is least in those arid regions in which customs are better adjusted to the values and interrelations of water. Under the English common law, prevailing in eastern United States, the water is held appurtenant to the land; under the Code Napoleon, prevailing in Louisiana, it virtually appertains to the community; under the Spanish-Roman law, prevailing in western United States, water is subject to prior appropriation and beneficial use, and hence appertains primarily to the individual or family, while the land is essentially appurtenant to the water traversing it.

Not being deemed a resource when our fundamental law was framed, the waters were in no wise granted by the people, except as employed in commerce under federal authority; and since their value has arisen through the natural growth and orderly development of our population and industries, they seem in equity to belong to the people collectively. When required by municipalities or communities, water is restrained and used as a matter of course, and the cost of the appurtenant land and works for its control is ordinarily borne by taxation offset by water rates, i. e., the water is appropriated and exploited, and then conveyed or sold as a commodity in the interests of the population supplied; and in all cases the investment (generally at first thought burdensome) proves either highly remunerative or inconsiderable in proportion to the benefits. When streams are controlled by individuals for power under federal grants, the power becomes a taxable commodity used, rented, or sold, certain rights being retained by the Federal Government in the interest of the people; and power developed by the nation in works connected with commerce is used, rented, or sold. Some States recognize a residuary right of the people in the natural waters, or in the headwaters of streams used for water supply or navigation, and this recognition seems to be extending over the country; but the usage of the different sections is not uniform, the exercise of the right of the people generally varying with the aridity of the land or the density of the population.

Since most navigable streams bound or traverse different Commonwealths, while the waters forming them are unstable and essentially interstate, the States generally have refrained from waterway improvement, save through a few canals and drainage projects; and since the headwaters on which the navigability depends are commonly intrastate, the Federal Government has refrained from assuming more than a partial and ineffective control of the navigable waters. Thus a half-hearted and irresponsible or repressive policy has grown up; navigation has been neglected and allowed to decline; both control of the running waters and recognition of their value have been delayed, and private monopoly has been permitted to invade to their detriment the source waters on which the rivers depend.

Some of our navigable and other waters are international, and questions of both civil jurisdiction and control or use of the flow have been or are being composed by treaty or convention sanctioned by laws of the nations in interest. In the Great Lakes and Columbia regions each second-foot of flow corresponds to about a square mile of land surface drained—i. e., an outtake of 10,000 second-feet involves relations equivalent to titular questions affecting 10,000 square miles of territory; and in the Rio Grande and Rio Colorado regions each second-foot of flow is equivalent to 20 or 25 square miles of territory.

It is now recognized by leading statesmen and experts that navigation is interdependent with other uses of the streams;[a] that each stream is essentially a unit from its source to the sea;[b] that the power of the Federal Government to improve navigable streams extends above the limit of navigability;[c] and that the benefits of a comprehensive system of waterway improvement will extend to all the people in the several sections and States of the country.[d]

It is also recognized, through the unanimous declaration of the governors of the States and Territories adopted in conference with the leading jurists, statesmen, and experts of the country, that in the use of the natural resources the independent States are interdependent, and bound together by ties of mutual benefits, responsibilities, and duties.[e]

It has recently been declared by a majority of our leading statesmen that it is an imperative duty to enter upon a systematic improvement, on a large and comprehensive plan, just to all portions of the country, of the waterways and harbors and Great Lakes whose natural adaptability to the increasing traffic of the land is one of the greatest gifts of a benign Providence; while a strong minority of the nation's statesmen indorsed the movement for control of the waterways more specifically and in equally emphatic terms.

Within recent months it has been recognized and demanded by a majority of the people, through many thousand delegates from all of the States assembled in conventions in different sections of the country, that the waterways should and must be improved promptly and effectively as a means of maintaining national prosperity, the cost to be borne either by federal appropriations or by the issue of bonds.

WHAT WE NEED TO DO

The first requisite for waterway improvement is control of the waters in such manner as to reduce floods and regulate the regimen of the navigable rivers; the second is development of terminals and connections in such manner as to regulate commerce.

---

[c] United States v. Rio Grande Irrigation Company (174 U. S., p. 690 et seq; also report of the Committee on the Judiciary on "Power of the Federal Government to acquire lands for national forest purposes" (60th Cong., 1st sess., H. R. Rep. 1514), p. 20.

[d] Preliminary report of the Inland Waterways Commission, 1908: "Findings," p. 24.

[e] Proceedings of the Conference of Governors, 1908, p. 193.

Most of the headwaters, especially in mountainous regions, may be so controlled by forestation as to diminish floods and ameliorate low waters, and at the same time clarify streams required for water supply and augment the subsurface reservoir of ground water. The effect of forest cover, with the attendant mulch, is to diffuse the rainfall and convert it into ground water, thereby reducing the surface run-off and holding the water back for use in plant growth or in seepage run-off through clear springs and brooks serving to maintain the rivers during dry periods, while the evaporation from the plants serves to increase the rainfall. Under proper management these benefits may be made self-sustaining through increased production.

Most lowland headwaters are on agricultural land, and are subject to control by judicious farming. Since no upland farm receives sufficient rainfall for the highest productivity, every acre should be made to utilize all the water reaching it. This may be effected by deep plowing and proper selection of crops on level land, by contour cultivation and terracing on rolling land, by dust-mulching on arid land, and by other devices of scientific farming. Thereby storm freshets may be cut off, the reservoir of ground water augmented, the springs and wells maintained, and the streams clarified and kept up during dry periods. The devices should be made not only self-supporting, but a source of increased production and profit.

About commercial centers and in populous districts, the paramount use of water is for domestic and manufacturing purposes; and the requisite supply should continue to be appropriated with the appurtenant lands and controlled under consistent State laws and federal regulations in the direct interest of the people. The catchment areas should be protected by proper covers of forest, grass, or other crops yielding reasonable returns, in such manner as to prevent both floods and soil wash with consequent pollution of the reservoirs and menace to life. When supplies are taken from lakes or the ground-water reservoir, both the maintenance of the public health and other uses of the waters (including navigation) should be duly weighed under the principle of the greatest good to the greatest number for the longest time. Wise administration demands that the water-supply projects be made so nearly as possible self-supporting through collateral benefits in order that potable water, as a prime necessary of life, may be placed within reach of all.

Refuse from household, farm, factory, mine, and city should be prevented from polluting streams, or extending needlessly into the ground water or contaminating the air. In rural households and communities refuse should be so treated as to yield high-grade fertilizer; urban sewage should be converted and utilized as a source of municipal revenue; and mine refuse should be treated as a by-product.

In arid and semiarid lands irrigation is (next to water supply) paramount, and all the water should be made available for the population dependent on each catchment basin. To this end the headwaters should be so controlled as to regulate the flow, the reservoirs should be large enough to store the surplus and prevent waste, and navigation should be limited to reservoirs and canals. Each irrigation project should be self-supporting; and any surplus or return water should remain in the natural channels available for other uses pending complete consumption in irrigation.

The navigable streams, partly controlled through their headwaters, should be further regulated by lock dams, movable dams, reservoirs, and other engineering devices found expedient in particular cases. They should be administered under federal regulations in the interest of the people, either independently or in cooperation with States, municipalities, communities, corporations, or individuals, as may be found expedient in particular cases. The projects should comprise such terminals and sites and such regulation thereof as may be essential to commerce. Drainage projects should be adapted, so far as practicable, to aiding in the control of the waters for navigation and related purposes.

When necessary, provision should be made for levees, jetties, hurdles, wing dams, revetment, mattressing, dredging, and other means of temporary and supplementary control of the waters and channels; and both the works and their sites should be acquired and protected under federal or State authority.

When consistent with other uses of the waters, fish should be propagated and protected in streams and lakes, and necessary fishways should be provided in connection with dams and other works; and State and federal laws relating to fish and fisheries in inland and coast waters should be unified.

In the design and construction of works connected with water supply, irrigation, navigation, or the control of water for other purposes, consideration should be given to the power developed thereby and to the equity of the people in this value of the waters; and all benefits derived from power in connection with works installed at the public cost should be applied to the public welfare through protection against loss or diminution of the cost of additional works, or in other proper ways.

In considering the benefits to be derived from the 215,000,000,000,000 cubic feet of water annually received, the paramount use should be that of water supply; next should follow navigation in humid regions and irrigation in arid regions. The utilization of power from the navigable and source streams should be kept subordinate to the primary and secondary uses of the waters, though, other things equal, power development should be encouraged, not only to reduce the drain on other resources, but because properly designed reservoirs and power plants retard the run-off and so aid in the control of the streams for navigation and other uses.

The broad plan already framed by statesmen and experts and approved by the Executive should be put in effect. It provides for a system of waterway improvement extending to all of the uses of the waters and benefits to be derived from their control, including the clarification of the water and the abatement of floods for the benefit of navigation, the extension of irrigation, the development and application of power, the prevention of soil wash, the purification of streams for water supply, and the drainage and utilization of the waters from swamp and overflow lands; and that the work shall be carried on by existing agencies in the federal departments under an administrative commission or board to be appointed by the President, acting in cooperation with States, municipalities, communities, corporations, and individuals.[a]

The improvements should conform to the plan already outlined.[b] In the Atlantic-interior system there should be a deep waterway from Gulf of Mexico to the Great Lakes and a deep and continuous Atlantic inner passage from New England to Florida, the present plan for improving the Ohio should be carried out promptly and should be perfected by any forestation and reservoirs required to control the headwaters, the upper Mississippi and the Missouri should be improved and canalized, the lower Mississippi should be connected with the Rio Grande and with the waters of Florida by inner passages, the navigable rivers flowing into Gulf of Mexico and Atlantic Ocean should be improved, and all appropriate links in the system should be adapted to vessels of standard depth and should be connected with one another and with the Great Lakes by canals of standard dimensions. In the Columbia-Puget system the rivers should be improved and requisite connecting canals should be constructed; and in the California system Sacramento, San Joaquin, and Feather rivers should be so improved as to open the country to interstate and foreign commerce.

To promote and perfect the plan, scientific investigations, surveys, and measurements should be continued and extended, especially the more accurate determination of rainfall and evaporation, the investigation and measurement of ground water, the gauging of streams and determination of sediment, and topographic surveys of catchment areas and sites available for control of the waters for navigation and related purposes.

It has been roughly estimated that the inland waterways of the country could be improved in ten years at a cost of $50,000,000 annually in such manner as to promote interstate commerce and at the same time greatly reduce the waste and extend the use of the waters. If done at the cost of the people, the burden would be 62½ cents per capita per year, or $6.25 in all, for a population of 80,000,000. This burden should be assumed without delay either by appropriations or by the issue of bonds in small denominations bearing low interest, adapted to distributing both the burden and benefits among the people.

It is roughly estimated that the direct benefits would comprise an annual saving in transportation of $250,000,000; an annual saving in flood damage of $150,000,000; an average annual saving in forest fires of at least $25,000,000; an annual benefit through cheapened power of fully $75,000,000; and an annual saving in soil erosion (or corresponding benefit through increased farm production) of $500,000,000—a total of $1,000,000,000, or $12.50 per capita annually, i. e., twenty times the cost. In addition, large benefits would result from extended irrigation, from the drainage and settlement of swamp and overflow lands, and from purified and cheapened water supply with consequent diminution of disease and saving of human life.

Various indirect benefits would arise through the interrelations among the natural resources. For example, the development of water traffic in lieu of rail carriage would reduce the constantly increasing consumption of ties and mine timbers, now a heavy drain on our forests; it would reduce the consumption of iron, since water vehicles require but a quarter to a third of the metal required by rail vehicles of like capacity; and it would correspondingly reduce the consumption of coal for both propulsion and smelting. At the same time the reduced use of ties and mine timbers would save the forests and so aid in protecting the headwaters on which the navigable streams depend for both supply and regimen.

---

[a] Preliminary Report of the Inland Waterways Commission, 1908: "Recommendations," pp. 25–27.

[b] Ibid.: "Inquiries in Progress," p. 29.

With a view to promoting interstate commerce, the Federal Government has aided railways by subsidies and grants to the extent of many hundred million dollars, thereby contributing materially to the 228,000 miles of railways and collateral property aggregating about one-seventh of our national wealth and earning nearly $2,500,000,000 annually; yet although our railway freightage runs only about three-quarters of a cent per ton-mile (or half that of Europe), our distances are so great that many commodities can not be moved with profit to and from our ports, and our export of foodstuffs have declined to the disturbance of our foreign commerce. Our farm and forest products exceed $8,000,000,000, our mineral products are $2,000,000,000, and our products of manufacture are fully $15,000,000,000 annually, or a gross nominal output (with considerable duplication) of $25,000,000,000. Of this aggregate, much is not moved by rail, and much more is moved short distances only; yet we paid for railway freightage alone in 1906 no less than $1,659,925,643. Reckoning the total cost of domestic traffic by rail and water and wagon, together with freightage on imports, it is probable that an average American family pays for transportation of food and clothing nearly or quite one-third of their actual cost, i. e., our consumers pay too much and our producers get too little for the necessaries of life. This condition would be relieved, while the railway business would be promoted rather than injured, by the development of water transportation on an adequate scale. The promotion of interstate commerce by railway aid was wise and beneficent in its time; but it is now time to supplement this agency of commerce by others better adapted to our multiplied population and enormously increased production.

It is estimated that the income derived from power developed by works for the improvement of navigation, if utilized at current market rates in cooperation with States and citizens, would alone compensate the entire cost of maintenance and continued development after the initial expenditure of $500,000,000 as a working capital. In any event the first cost should be deemed an investment in the interest of the people, certain to yield large returns in public welfare and national growth.

Whether or not the initial investment be so made as to yield pecuniary returns, the just and reasonable demand of a majority of the people for the improvement of their waterways should be met, and that the more promptly by reason of seventy years of repression.

W J McGee,
Secretary, Section of Waters.

FORESTS.

WHAT FORESTS DO.

Our industries which subsist wholly or mainly upon wood pay the wages of more than 1,500,000 men and women.

Forests not only grow timber, but they hold the soil and they conserve the streams. They abate the wind and give protection from excessive heat or cold. Woodlands make for the fiber, health, and happiness of each citizen and of the nation.

The fish which live in forest waters furnish each year $21,000,000 worth of food, and not less than half as much is furnished by the game which could not exist without the forest.

The industries which use wood wholly or mainly in manufacture represent an investment of over $2,250,000,000 and yield each year a product worth nearly $3,000,000,000.

Forests conserve streams by regulating their flow. Our knowledge of the effect of forests upon the quantity of water carried by streams is not yet complete. Our knowledge of the effect of forests upon the regularity of stream flow has an adequate basis of observation and record.

We do not possess complete scientific proof that forests increase rain, but known laws governing rainfall and the known physical effects of forests lead straight to that conclusion. A part of the falling rain or snow is checked by the tree tops and returned to the air by evaporation. But this evaporation is wholly or nearly compensated for by the smaller evaporation from the soil under forest cover than from the soil in the open. The forest soil gives up water to the air more slowly than either brush land, meadow land, or cultivated fields.

Both observation and record show fully that forests powerfully affect the manner in which water reaches streams and passes down them. The forest floor is a blanket, and like a blanket it will hold more water than will the harder and relatively less porous soil of the open. A saturated forest soil will hold more than half its dry weight in water, or over 6 inches of water for every foot of soil. This, as well as the breaking up of forest soil by the roots of trees and undergrowth, makes it more effective than any other cover for the intake of water into that vast underground reservoir from which all streams and springs are fed.

When the forest is cleared from a mountain watershed the blanket formed by the decaying leaves, branches, and fallen trees is burned up, dried by the sun, or carried off by wind and water. This is inevitably followed by increase in the frequency and duration of floods. This fact is known to every man who has had an opportunity to observe it. To those who have not had this opportunity the story is told by actual record of stream flow upon the following rivers for a period during which the mountain forests on their watersheds were rapidly denuded. These are such as the Ohio, Monongahela, Allegheny, Cumberland, Alabama, Savannah, Wateree, Congaree, and Muskingum.

That surface conditions affect stream flow is shown by the record of streams whose naturally treeless watersheds by cultivation have been made more retentive of water. The principal watershed of the Red River lies in the prairie country of western Texas and Oklahoma. With slightly decreased rainfall this stream shows during the last sixteen years a marked decrease in the frequency and duration of floods and of low water. During this period much of its watershed has been cultivated, groves have been planted, and fires checked, resulting in a larger capacity for the absorption and storage of water.

That forests hold soil and that hillsides denuded of forest do not hold their soil is to be seen in any mountain region in the United States. One small stream has been found by actual measurement to deposit silt in one year equal to 1½ tons per acre of its watershed. For the whole United States the loss of soil each year is from one to two thousand million tons. At the lowest estimate the total quantity of silt carried by our streams would cover 1 foot deep a surface of more than 900 square miles. The larger part of it is deposited in the lower courses of our streams and in our harbors, a menace to navigation and to present developed water powers, and a handicap to their development.

The National Forests in the Rocky Mountain and Pacific coast States afford summer ranges to over 12 per cent of the cattle and 21 per cent of the sheep in the States in which they lie. If this live stock were not fed in the forests during the summer months it would be without natural forage during the winter. For the East, the number of forest-fed live stock can not be given. But notably in the southern pine belt and in the southern mountains, live-stock owners, especially small holders, turn out their sheep, cattle, and hogs in the forests for the larger part of each year.

That the existence of nearly all kinds of wild game depends directly upon the conservation of the forest is well known. The deer killed in six States alone in the northeast represents each year a food value of over $1,000,000. The raw furs exported yearly from the United States are worth $7,000,000 to $8,000,000, and raw furs worth in the aggregate still more are kept for manufacture here. Most of these furs are taken from forest animals. Relatively few kinds of fresh-water fish, and mainly those of inferior food value, will endure in streams fed from denuded watersheds.

WHAT WE HAVE.

Our forests now cover 550,000,000 acres, or about one-fourth of the United States. The original forests covered not less than 850,000,000 acres.

Forests publicly owned contain one-fifth of all timber standing. Forests privately owned contain at least four-fifths of the standing tim-

ber. The timber privately owned is not only four times that publicly owned, but it is generally more valuable.

Forestry is now practiced on 70 per cent of the forests publicly owned and on less than 1 per cent of the forests privately owned, or on only 18 per cent of the total area of forests.

The original forests of the United States contained timber in quantity and variety far beyond that upon any other area of similar size in the world. They covered 850,000,000 acres, with a stand of not less than 5,200,000,000,000 board feet of merchantable timber, according to present standards of use. There were five great forest regions—the northern, the southern, the central, the Rocky Mountain, and the Pacific. (See fig. 1.)

The northern forest was the home of the white pine. With it grew red pine, spruce, hemlock, cedar, balsam fir, and several hardwoods. Before clearing and logging began, the northern forest probably covered 150,000,000 acres, and contained not less than 1,000,000,000,000 board feet. In the southern forest the yellow pines were the most common trees, with hard woods on the better soils and cypress in the swamps. The southern forest probably covered 220,000,000 acres and contained at least 1,000,000,000,000 board feet. The central forest was nearly all hardwoods, among which the more important were oak, yellow poplar, elm, hickory, chestnut, red gum, ash, and walnut. Its area was about 280,000,000 acres and its stand 1,400,000,000,000 board feet. The Rocky Mountain forest was coniferous and grew mainly upon the mountains. Western yellow pine was the most common tree, with lodgepole pine, larch, spruce, western red cedar, western white pine, and Douglas and other firs abounding locally. The Rocky Mountain forest covered about 110,000,000 acres with a stand of 400,000,000,000 board feet. The Pacific forest was nearly all evergreen, chiefly Douglas fir, western yellow pine, redwood, western red cedar, sugar pine, and several other firs, cedars, and spruces. Its trees were the largest and its stands the heaviest recorded by history or by geology. The Pacific forest probably contained 90,000,000 acres, with a stand of 1,400,000,000,000 feet.

As well as these great forest regions, the United States probably contained 100,000,000 acres, chiefly in the West, of scrubby forests and brush land, of great value in conserving stream flow and for fuel, posts, and other small material.

Our present forests, except upon the Pacific coast and in the Rocky Mountains, are mere remnants of those which once covered 45 per cent of the country. Clearing for agriculture, logging, and fire have reduced this to 29 per cent, or 550,000,000 acres, with a probable stand of 2,500,000,000,000 board feet. The northern forest now contains 90,000,000 acres, or 60 per cent of its former area; the southern forest 150,000,000 acres, or 68 per cent; the central forest 130,000,000 acres, or 46 per cent; the Rocky Mountain forest 100,000,000 acres, or 91 per cent; and the Pacific forest 80,000,000 acres, or 89 per cent of its original acreage.

Fire, careless cutting, and excessive grazing have greatly injured the composition and quality of existing forests. No native tree has yet become entirely extinct, but the commercial supply of every kind, except those of the Pacific forest, is seriously reduced. The following estimates of the quantity of timber publicly and privately owned have been compiled by the National Conservation Commission.

Forests publicly owned are nearly all in the West. (See fig. 2.) They consist of National Forests, national parks, Indian reservations, military reservations, the forests of the unreserved public domain, and state forests. They contain over 100,000,000 acres of merchantable timber, with a stand of 484,200,000,000 board feet, distributed as follows:

Public forest lands.

		Total stand.
In national forests	board feet	390,000,000,000
In national parks	do	11,000,000,000
In unreserved public domain	do	14,000,000,000
In Indian reservations	do	34,000,000,000
In military reservations	do	200,000,000
In state forests	do	35,000,000,000
Total	do	484,200,000,000

Forestry is practiced on 70 per cent of these public forests.

Forests privately owned fall into two classes—farmers' woodlots and larger private holdings. Woodlots contain 300,000,000,000 board feet of saw timber and 1,500,000,000 cords of wood. They cover 200,000,000 acres, 95 per cent of which is in the region east of the plains, where woodlots form about one-half the forest. Woodlots consist in the main of scattered patches of original forest, from which the best timber has been cut. They are made to yield little saw timber, but furnish the chief supply of fuel, posts, and rails, and of wood for other domestic and some local uses. Particularly in the East woodlots furnish a considerable number of hewn ties. Through their location among farm lands and their small individual area, woodlots suffer less damage from fire than do large timber tracts. But they are seldom conserved by the regulation of either cutting or grazing.

Corporate holdings with the larger individual holdings contain about 1,700,000,000,000 feet of timber. This is, on the average, the most valuable timber in the United States. Forestry is practiced on much less than 1 per cent of the timber tracts privately owned.

WHAT IS PRODUCED.

The yearly growth of wood in our forests does not average more than 12 cubic feet per acre. This gives a total yearly growth of less than 7,000,000,000 cubic feet.

Nearly all our native commercial trees grow much faster than those of Europe. We already grow post timber in twenty to thirty years, mine timber in twenty-five to thirty-five years, tie timber in thirty-five to forty years, and saw timber in thirty to seventy-five years.

We have 200,000,000 acres of mature forests, in which yearly growth is balanced by decay; 250,000,000 acres partly cut over or burned over, but restocking naturally with enough young growth to produce a merchantable crop; and 100,000,000 acres cut over and burned over, upon which young growth is either wholly lacking or too scanty to make merchantable timber.

That our forests grow very slowly, although the individual trees of many kinds grow fast, is our fault. In Europe, forests composed of trees growing much slower than most of ours produce over four times as much because the forests are cared for.

FIG. 4.

We have twenty important kinds of trees which produce in one hundred years or less, timber fit for the saw. In favorable localities, cottonwood, red gum, white ash, and loblolly pine in the South, and redwood, Douglas and other firs, Sitka spruce, and western yellow pine on the Pacific coast, will grow saw timber in thirty to seventy-five years.

Under present conditions, chestnut, cypress, redwood, yellow poplar, red and black oak, loblolly, jack, red and white pine, and western yellow pine will grow post timber, four to eight inches in diameter, in fifteen to thirty years. We are already getting mine props in twenty-five to thirty-five years from red or black oak and loblolly pine, from white oak in forty-five years, from red pine in forty years, from lodgepole pine in sixty years, from western yellow pine and Douglas fir in the Rocky Mountains in fifty years and on the Pacific coast in thirty-five years.

The time now needed to grow a tie in our forests runs from thirty-five years for red gum to one hundred and fifty years for white cedar and tamarack in the northern swamps. Douglas fir and western yellow pine on the Pacific coast, and chestnut, red oak, and loblolly pine are, on the average, making tie timber in forty to forty-five years, cypress in sixty-five years, longleaf pine in seventy-five years, white oak in eighty years, lodgepole pine in the Rockies, and beech, in 100 years, and western hemlock in one hundred and thirty years.

These figures are taken from measurements of trees grown in forests not conservatively managed. In the same forests, conservative management would, as the result of greater density, less unsoundness, and the growing of desirable kinds, not only yield several times as much timber in the same period, but would increase the growth of individual trees.

The 200,000,000 acres of mature forest in the United States is mainly in the northern Rockies and on the Pacific coast, the very regions in which the immature forests grow most rapidly. The 250,000,000 acres partly cut or burned over but restocking naturally with young growth are mostly in the southern mountains and in the southern pine belt. The 100,000,000 acres cut over and burned over, upon which young growth is wholly lacking or too scanty to make merchantable timber, are chiefly in the Lake States and in the southern pine belt.

WHAT IS USED.

We take from our forests yearly, including waste in logging and in manufacture, 23,000,000,000 cubic feet of wood.

We use each year 100,000,000 cords of firewood, 40,000,000,000 board feet of lumber, more than 1,000,000,000 posts, poles, and fence rails, 118,000,000 hewn ties, 1,500,000,000 staves, over 133,000,000 sets of heading, nearly 500,000,000 barrel hoops, 3,000,000 cords of native pulp wood, 165,000,000 cubic feet of round mine timbers, and 1,250,000 cords of wood for distillation.

The volume of wood needed in 1907 to produce each of these great products is shown graphically in figure 3. The kind and quality of timber used for these products vary enormously. The great bulk of firewood comes from farmers' woodlots or from forests already logged. Some of it is made from wood unfit for any other use. But a large part is taken from immature trees, especially hardwoods of kinds valuable for lumber.

Lumber and shingles are usually made from large timber of high quality. Lumber is being made in commercial quantities from thirty kinds of trees. The amount cut from each of them is shown in figure 4. Softwoods furnish 77 per cent of our total yearly lumber supply, and hardwoods 23 per cent.

The southern pines furnish over 30 per cent of our lumber; Douglas fir about 12 per cent; white pine, 10 per cent; oak, 9 per cent; and hemlock over 8 per cent.

The lumber cut in 1907, by States, is shown in figure 5. Washington was first, with 9.4 per cent; Louisiana second, with 7.4 per cent; Texas came next, with 5.5 per cent; and Mississippi, Wisconsin, and Arkansas followed closely, with about 5 per cent each.

The center of lumber supply in the United States shifts constantly, as one region is cut over and another is attacked. The relative production of ten States in 1880 and 1907 is shown in figure 6.

In 1880 these ten States produced 53.8 per cent of the total cut of 18,125,432,000 board feet, and in 1907 they produced 52.4 per cent of the total cut of 40,256,154,000 board feet. The changes in the output by States are striking. Michigan supplied 23 per cent of the total lumber output in 1880 and 4.5 per cent in 1907. Washington yielded less than 1 per cent in 1880 and over 9 per cent in 1907.

Over three-fifths of our shingles are made from western red cedar, chiefly in Washington, and the remainder mainly from eastern white cedar, cypress, and redwood. Telephone, telegraph, and electric light and traction companies use each year between three and four million poles in various lengths above 20 feet. Three-fifths of these are white cedar, cut chiefly in the Lake States, and over one-fourth is chestnut. Much cedar and chestnut, as well as many woods common to other regions are used for smaller-sized poles and for posts and fence rails. The oaks, chiefly white oak, furnish over 45 per cent of the hewn railroad ties. The cutting of young oak for ties, next to the cutting of oak logs for lumber, is the most serious drain upon our oak forests. Other kinds much used for ties are the southern and western pines, cedar, chestnut, cypress, and hemlock. Many woods are used for slack cooperage stock, of which the chief are red gum, pine, elm, beech, and maple. A large part of the tight cooperage stock is high-grade white oak, which results in another heavy drain upon the oak forests.

Our paper and pulp mills use over 3,000,000 cords of native wood each year and import more than 900,000 cords from Canada. Nearly three-fifths of the native pulp wood is spruce, cut mostly in the Northeastern States, and one-fifth is hemlock, which comes chiefly from Pennsylvania and Wisconsin.

The cutting of mine timbers takes each year great quantities of immature timber from forests in the mining regions, the kinds used varying with the locality.

Nearly all wood used for distillation is beech, birch, and maple. In relatively few cases this wood is saved from the waste in logging.

WHAT IS WASTED.

Since 1870 forest fires have each year destroyed an average of fifty lives and $50,000,000 worth of timber. Not less than 50,000,000 acres of forest are burned over yearly. The young growth destroyed by fire is worth far more than the merchantable timber burned.

One-fourth of the standing timber is left or otherwise lost in logging. The boxing of longleaf pine for turpentine has destroyed one-fifth of the forests worked. The loss in the mill is from one-third to two-thirds of the timber sawed. The loss in the mill product through seasoning and fitting for use is from one-seventh to one-fourth. Great damage is done by insects to forests and forest products. An average of only 320 feet of lumber is used for each 1,000 feet which stood in the forest.

Prodigious waste has accompanied our use of the forest. The chief causes are fire, wasteful methods of logging and turpentining, waste in the mill, and waste in the use of wood.

Forest fires have destroyed many billion feet of commercial timber. They have driven the forest from vast areas, upon which the actual planting of trees will be needed before the forest will return to them. They have destroyed or injured young growth whose value is much more than that of the timber burned. They have changed greatly for the worse the quality and composition of existing forests. To them is due, far more than to the wasteful logging which they have usually followed, the decline in the utility of our streams for all useful purposes; and, through erosion, forest fires are working destructive change in the configuration of the land itself.

The average waste in the woods is 1,000 board feet to every 4,000 board feet logged. This is due to a variety of causes, many of which could be wholly removed with both present and permanent profit, and all of which could be greatly reduced with the same result. Chief among them are plans for logging poorly made or poorly carried out; the leaving of merchantable timber in the woods either actually cut or in dead trees, trees partly unsound, or trees of the less valuable kinds; the waste of timber in high stumps and long tops, and in the failure to cut logs to such lengths that the tree is most profitably used; breakage in felling, loss in lodged trees, and in driving; and the use of good timber for temporary construction in logging, for which inferior timber would serve equally well. But still more serious than all these forms of waste combined, in its effect upon the future timber supply, is the well-nigh universal damage in logging, for the most part wholly unnecessary, to the young growth.

The experience of half a century has clearly shown in Virginia, the Carolinas, and Georgia that turpentining under present methods renders a permanent naval-stores industry in the South utterly impossible. These methods usually render the forest unproductive in four or five years. They have so greatly reduced the longleaf-pine forests available for turpentining that in some localities trees 4 or 5 inches in diameter are now being boxed. This generally means an exceedingly low return in turpentine and the death in a year or two of trees, which would otherwise have grown to make lumber.

In the mill logs lose from 30 to in some cases as much as 70 per cent of the volume of timber they contain. Two-thirds of this, under present conditions, is an unavoidable waste. One-third can practically and profitably be avoided. In the manufacture of lumber, which forms over nine-tenths of the total mill product, the merchantable output is about two-thirds the contents of the log, not including the bark. For the entire lumber cut of the United States under present practice the saw kerf forms on the average 13 per cent of the total volume of the log, edgings and trimmings 9 per cent, and slabs 9 per cent. Cutting to standard lengths and widths, carelessness in manufacture, and accidents cause a loss of 5 per cent.

The waste in seasoning, in the factory, and in the use of the final product is far more difficult to estimate closely. In the building trades the waste in seasoning from staining, warping, and checking, and the loss in fitting material to final forms are not less than 15 per cent. The waste in cutting stock to required sizes and in eliminating defects is 20 per cent in box factories and 25 per cent in furniture factories.

In the aggregate great damage is done each year to standing and cut timber by injurious forest insects. Much of this damage can be prevented at small expense. The application, practically without cost, of simple preventive measures against injurious forest insects and insects which attack forest products would greatly reduce the unnecessary losses which they occasion. The protection of the forest from insect depredations, both by preventive measures such as conservative logging and by remedial measures when necessary, is no less a part of practical forestry than is the protection of the forest from fire. The damage to timber standing and cut by insect attack is not so generally apparent nor so generally understood as the damage to the forest by fire. But the injury done is both great and constant. Unless forest owners take vigorous steps against it wherever it threatens still larger losses will inevitably ensue.

Great causes of waste, vast in their effect upon our forests, are the general failure to realize that the cost of growing timber as well as logging and manufacture must be reckoned in its value; and tax laws which force men to realize immediately on their holdings and so lead to unprofitable and wasteful logging, and which compel the abandonment of cut-over lands for taxes.

WHERE WE STAND.

We take from our forests each year, not counting the loss by fire, three and one-half times their yearly growth. We take 40 cubic feet per acre for each 12 cubic feet grown; we take 260 cubic feet per capita, while Germany uses 37 cubic feet and France 25 cubic feet.

We invite by overtaxation the misuse of our forests. We should plant, to protect farms from wind and to make stripped or treeless lands productive, an area larger than that of Pennsylvania, Ohio, and West Virginia combined. But so far, lands successfully planted to trees make a total area smaller than Rhode Island. And year by year, through careless cutting and fires, we lower the capacity of existing forests to produce their like again, or totally destroy them.

The condition of the world supply of timber makes up already dependent upon what we produce. We send out of our country one and one-half times as much timber as we bring in. Except for finishing woods, relatively insignificant in quantity, we must grow out own supply or go without.

By wasteful logging, fire, and general failure to provide for a second crop we have made our forests less productive than any others of similar area in the world, in spite of the remarkably quick growth of most of our timber trees. We have taken our dividends out of our forest capital until we have greatly reduced the capital itself. Our use of wood per capita is larger than that of any other nation. Canada, which has 60 acres of forest per capita to our 6, uses less than 200 cubic feet per capita; Germany uses 37 feet, France 25 feet, and Great Britain 14 feet. We use 260 cubic feet.

We have 65,000,000 acres of cut-over and burned-over forest land, upon which actual planting will be necessary to produce a merchantable crop of timber. Of the 9,500,000 acres of forest cut over each year, 1,000,000 acres is cleared for farms; 5,750,000 acres is restocking naturally with enough young growth to produce a merchantable crop; and 2,750,000 acres go to increase our national task in forest planting. But the entire area already planted successfully in our whole history is less than one-fifth of that upon which we destroy the forest every year.

White pine is so nearly used up that the lumber sawed from it in the Lake States has fallen off 70 per cent since 1890, and since 1900 over 45 per cent in the whole country. We make 16 per cent less oak lumber and 22 per cent less yellow poplar lumber than we did seven years ago. Douglas fir and yellow pine, now our chief source of supply, are going far quicker than they grow, and the yellow pine is going very rapidly. Yellow pine lumber costs 65 per cent more at mill than it did in 1900; Douglas fir costs 63 per cent more; white pine 53 per cent more; oak 54 per cent, yellow poplar 78 per cent, and hemlock 55 per cent more.

We tax our forests under the general property tax, a method of taxation abandoned long ago by every other great nation. In some regions of great importance for timber supply, and in individual cases in all regions, the taxation of forest lands has been excessive and has led to waste by forcing the destructive logging of mature forests, as well as through the abandonment of cut-over lands for taxes. That this has not been even more general is due to under-assessment, to lax administration of the law, but to no virtue in the law itself. Already taxes upon forest lands are being increased by the strict enforcement of the tax laws. Even where this has not yet been done, the fear that it will be done is a bar to the practice of forestry.

The protection of all public forests from fire is not yet achieved, and an average of 1 acre in every 10 of forest privately owned is burned over yearly. Many of these fires destroy little or no old growth, but wherever fire runs in our forests it either reduces or destroys their capacity to produce again.

We send wood out of the country, and we bring it in. But for each billion feet brought in we send out 1,500,000,000 feet, and the total difference goes to increase by nearly 1 per cent the yearly drain upon our forests. No other country is or will be in a position to meet our needs. Europe imports more wood than she exports. Africa imports structural timber, and can export only expensive hardwoods. The same is true of India, the chief forest country of Asia. China imports wood, and will require any surplus furnished by Siberia and Manchuria. Japan should finally supply her own needs. The Philippines now import much timber, but should eventually grow it, with some surplus for export to China. The total stand of merchantable timber in the Philippines is about equal to the lumber cut in the United States for two years. Alaska has probably as much as the Philippines. Hawaii can export only hardwoods in small quantities. Mexico and Central and South America import structural timber and export mahogany and cedar. South America has great forests which when utilized and cared for should supply the home market. We get about 900,000,000 feet of lumber and 900,000 cords of pulp wood from Canada each year, or 2 per cent of the lumber and 23 per cent of the pulp wood which we use. Canada has more spruce pulp wood than we have, but her standing saw timber is only about one-third of ours. Canada will eventually require all the lumber which her forests can grow.

Whether we take care of our forests, or whether we do not, we can expect (save for a trifling quantity of finishing woods) to use what timber they grow, and no more.

The records prove that, other factors remaining constant, industrial progress is accompanied by increased consumption of wood. This fact is so universally manifest that it can not be thought an accident. It may be regarded as a law of industrial life.

It might be supposed that the substitution of other materials for wood which takes place with industrial progress would decrease the per capita need of wood, but such is not the fact. Substitutions may diminish consumption for specific purposes, but this is more than made up for by the development of needs for wood along new lines or of greater needs along old lines. Only rising prices can serve to lessen the consumption of wood by an advancing nation, and after wasteful use has been cut off, any further reduction means an economic disadvantage. It means harder conditions of life, a handicap on industry.

In the United States our use of wood is lavish. By better methods in the woods, at the mill, and in ways of use we can make what we have go further than we are now making it go, without industrial hardship. On the other hand, our legitimate need will certainly not decline but advance as we go on to greater industrial strength. We can without hardship reduce our per capita consumption through economies; but after we have reached a reasonable basis we must expect to see our needs advancing again. We are like a growing family which is extravagantly living beyond its income, but which is sure to need, when it has cut off extravagant use, an advancing income through future years.

WHAT SHOULD BE DONE.

We should stop forest fires. By careful logging we should both reduce waste and leave cut-over lands productive. We should make the timber logged go further by preservative treatment and by avoiding needless loss in the woods, the mill, the factory, and in use. We should plant up those lands now treeless which will be most useful under forest. We should so adjust taxation that cut-over lands can be held for a second crop. We should recognize that it costs to grow timber as well as to log and saw it.

We should continue and perfect, by State and nation, the preservation by use of forests already publicly owned; and we should extend it to other mountain forests more valuable for the permanent benefit of the many than for the temporary profit of a few.

For each million acres of forest in public ownership over 4,000,000 are privately owned. The conservation of public forests is the smaller task before the nation and the States. The larger task is to induce private forest owners, which means 3,000,000 men, to take care of what they have, and to teach wood users, which means every one, how not to waste.

If these things are done, they will conserve our streams as well as our forests. If they are not done, the usefulness of our streams will decrease no less than the usefulness of our forsets.

THE DUTY OF THE PRIVATE OWNER.

Four-fifths of our standing timber is in private hands. The conservation of our forests and of the timber used depends mainly upon individual forest owners and users. If American citizens will protect their forests from fire, will provide by conservative logging for a good second crop, and will take every reasonable precaution against the waste of timber in the woods, in the mill, in the factory, and in use, their forests will eventually supply more than their need, continuously. If these things, each one of which will pay now and in the future as well, are not done, this nation will ultimately be dependent upon public forests. These, if cut absolutely clean, would furnish only enough lumber to meet our national need for ten years. At the end of that time they would be exhausted. If we are to be saved from great suffering for lack of timber, the forests of private owners must supply the timber.

STOPPING FOREST FIRES.

Forest fires are preventable at a cost slight in itself and insignificant compared with the value of the timber they destroy. Experience on the National Forests has shown that the way to keep down fires is to employ men to watch for them during the fire season. An expenditure of a few hundred dollars in employing men to patrol during the dangerous part of the year is vastly more effective than the expenditure of many times this sum in the attempt, often futile, to put out fires already under headway.

The cost per acre of protecting the forest from fire varies directly with the density of settlement, with local sentiment, with the character of the country and of the forest, with the means of transportation and communication, and with the length of the fire season.

Studies made by the Department of Agriculture and the experience of private owners who are protecting their forests from fire show that the forests of the southern mountains and of the southern pine belt can be effectively patrolled for 2 cents per acre per year. The northern forests can be patrolled thoroughly for not more than 4 cents per acre, and the Rocky Mountains and Pacific coast forests for 1½ cents per acre. These estimates mean, if their owners would cooperate effectively, that all forests in private hands in the United States can be protected from fire for less than $10,000,000 a year—about the cost of one *Dreadnought*. It also means that at an expenditure of $10,000,000 a year, a yearly loss in merchantable timber of about $50,000,000 would be prevented. This does not count the saving in young growth.

The best methods of fire protection for private owners vary greatly with the conditions which fix its cost. But for all regions the following principles are sound on tracts of some size:

1. Employ an adequate force whose first duty is to patrol against fires. Give them all the tools they need, and mount them if they can so work more effectively. In the South and in the Rocky Mountains a mounted patrol is best. In many parts of the northern and Pacific forests, men can do their best work on foot.

2. Increase the efficiency of the fire-fighting force and reduce its size by building trails for patrol. Telephone lines can be built cheaply and if properly distributed throughout the forest, and combined with a good trail system, will increase several times the area which can be effectually patrolled by one man.

3. Build up a local sentiment against fires by making the damage they do plain to all.

4. Cooperate in fire patrol with other forest owners, Above all cooperate with those who own tracts contiguous to your own. This will render your patrol and theirs not only cheaper but vastly more effective.

FOREST PLANTING.

Forest planting means the protection of denuded watersheds from erosion, and the protection of farm homes and crops from wind and cold. In many localities, it means the production of timber near by instead of bringing it from a distance at much greater cost.

The United States contains 65,000,000 acres of stripped land, suitable only for the growing of trees, which will not bear a productive forest again except through the actual planting of trees, or sowing of tree seeds. The West contains 16,000,000 acres of naturally treeless land which should be planted to trees in the interest of agriculture in the prairie region and on irrigated lands elsewhere. Thus far, we have planted in all less than 1,000,000 acres, of which probably less than one-half is successful, because we have planted, for the most part, without adequate knowledge of where, what, and how to plant.

As regards the need for tree planting, the United States naturally falls into three regions—the Eastern, the Central, and the Western.

The Eastern region lies east of the prairie States. In it the planting of trees for the production of timber is of much more importance than for protection to stream flow or to crops. It contains lands of the following classes, which can be planted with profit to their owners:

Cut-over lands not good to farm, upon which, usually as a result of repeated fires after logging, natural reproduction is not taking place. Lands suitable only for forest, but which have been cleared, farmed unsuccessfully, and then abandoned. Woodlots in which planting is necessary to supplement natural reproduction or to take its place.

Cut-over and burned-over lands in need of planting aggregate 3,500,000 acres, and occur mainly in the Adirondack region and in the northern portion of the lake States; abandoned farm lands occur mainly in New England and in the southern mountains; unproductive woodlots are characteristic chiefly of the region west of the Appalachians and east of the prairies.

The Southern States contain about 12,000,000 acres upon which natural reproduction is insufficient or lacking, but upon which adequate fire protection will in the main restore good forest conditions. In the eastern region about 92,000 acres have been planted, of which 5,000 acres are state forest lands.

The Central region comprises the prairie country, which includes Illinois, Iowa, North Dakota, South Dakota, Nebraska, and Kansas, the prairie district of Minnesota, and those parts of Oklahoma and Texas which lie west of the hardwood belt. It contains about 14,000,000 acres, which should be planted to trees for the protection of crops from wind, to reduce evaporation, and to grow timber for farm and other local uses. Planting already covers 831,000 acres in this region, and wherever rightly done yields remarkably high profit.

The Western region includes the Rocky Mountain and Pacific coast States. In it the planting problem is mainly Federal. Not less than 5,000,000 acres or about 3 per cent of the area of the National Forests must be planted to protect watersheds, and to increase the production of timber. Southern California alone contains probably not less than 1,000,000 acres outside National Forests which are now unproductive and could be made productive under trees. Planting is necessary upon nearly 3,000,000 acres to protect crops on irrigated lands in the western region. Private owners have planted only 37,000 acres of such lands thus far. On national forests experimental planting and sowing has been done upon 1,762 acres. This has been carefully planned and carried out, and already furnishes the knowledge required for successful planting on a large scale, as soon as the necessary funds are available.

To sum up, our task in forest planting is vast. Thus far in actual acreage successfully planted our accomplishment is wholly inadequate. The area of naturally treeless lands already planted is utterly insignificant in comparison with their total extent. Upon denuded forest lands we have planted only 1 acre to each 10,000 we have to plant.

RECOGNIZING THE VALUE OF TIMBER.

We have manufactured more lumber and other forest products than we require. That is, we have established a consumption per capita, based not merely on actual need, but on a lavishness, a disregard for possible substitutes, and a scale of waste in the use of wood, equaled in no other country. Supply has been regulated to a demand swollen not so much by industrial development, great as it has been, as by a product unduly cheap, because the items of logging and manufacture were considered the main costs of producing it. The cost of growing the trees has always been left out.

That there is, in the economic sense, overproduction of lumber is wholly true, because we manufacture more lumber than our forests can yield permanently. No economic reason fully explains the difference between the price of lumber grown in the United States and of lumber grown in Europe. Difference in the density of population explains it only in part. But neither that nor the relation of supply to demand is the chief cause. It lies in our failure to realize that if we are to grow timber continuously to meet our needs its value must be reckoned by the cost of growing it as well as by the cost of logging and manufacture. Stumpage prices in the United States average less than one-fifth of the price of lumber at the mill. The value of anything which is needed is at least what it will cost to grow it again.

We pay generally less for lumber than it is worth, with a slight present gain to ourselves individually, and by so doing we discourage the right use of the forest and greatly increase the cost of lumber to ourselves later on, and to those who come after us. We must recognize the actual value of timber now, or pay an excessive price for it in the future, and we have carried destruction so far that we shall probably have to do both.

CONSERVATIVE TURPENTINING.

An important source of waste is boxing small trees, which yield little turpentine and soon die. If left standing, these small trees would make lumber and pay well. Another source of waste is boxing larger trees so deeply that they die in a few years or are blown down, while in the meantime the deep wound made in boxing invites fire. The cup and gutter method of turpentining, introduced by the Federal Government, yields 30 per cent more turpentine and better turpentine, does not invite windfall, and lessens injury from fire. Under this system, combined with other economies still more recently devised, a forest can probably be worked for fifteen to twenty years, and made to yield much more turpentine, with small injury to the merchantable timber.

If improved methods of turpentining are given general use in longleaf pine forests and in the working of other southern and western pines, they will mean both a permanent naval-stores industry, a higher profit to turpentiners, and an important gain in the continuous timber yield of our forests.

CONSERVATIVE LOGGING.

Through careless and destructive logging on private forest lands, an average of 25 per cent of the merchantable timber is left standing, or otherwise wasted in the woods. On National Forests, from which has been sold yearly for the last three years an average of about 250,000,000 board feet of timber, the total waste in logging is about 10 per cent. This timber was sold at prices no lower than those paid for timber of the same kind and quality on private forest lands. It was logged and manufactured by the lumbermen who bought it, and sold by them in the open market, in competition with lumber cut from private forest lands under wasteful methods. Last year the Federal Government was asked by lumbermen to sell at good prices, from National Forests, ten times as much timber as it sold. That it did not make more timber sales was partly because the force on National Forests was not large enough to handle them. But if lumbermen can with profit buy timber at what it is worth from the forest lands of the people, and log it conservatively, they can do at least as well with their own.

Part of the waste in logging is unavoidable under present conditions. The following discussion deals specifically with those items of waste which it is practicable to avoid now, often with higher immediate profit to the owner of the land from which the timber is cut, and always with higher permanent profit from the land itself after it is cut over the first time.

Care for young growth.—The loss to the value of the forest, through injury to young growth in logging, is larger than the waste of merchantable timber. A small part of this damage is unavoidable. Nearly all of it is avoidable without materially increasing the cost of logging. It costs no more money to fell a tree uphill than to damage young growth by felling it downhill. It does not cost much to release young trees bent over by the tops of felled trees. More logging roads, skidding paths, and snake trails than are really needed kill much young growth, and they do not make for cheap logging. Rolling logs down hill is seldom necessary, and it often breaks down young trees which are worth more than the log is worth, to the lumberman who means to hold his cut-over land, or to the men to whom he sells it. Young trees are worth at least as much as it costs to replace them, or about $10 an acre; and $10 an acre spent in forest planting will seldom give us as good a forest as nature will grow for us, if we will take care of the young growth.

Leaving seed trees.—How many and what seed trees to leave, and where, depends on the cost of logging, on the character of the forest, and on the power of its most valuable trees to reproduce themselves. There are no general rules which apply to all forests. It is seldom necessary to leave prime timber as trees for seed. Unsound trees which will probably live long enough to seed up the area, scrubby trees already bearing seed, but unfit for lumber, and thrifty trees too small to be logged with the highest profit now, generally serve the purpose well.

The lumberman who claims that it does not pay to leave seed trees to shed seed, or to take care of young trees, because we may not live to harvest them, forgets these things: that second growth grows much faster than first growth; and that cut-over lands suitable only for forest purposes, which bear young growth, already have a good market value, while cut-over lands bearing neither timber nor young growth have little or no value.

Saving immature trees.—Poor grades of lumber come chiefly from small trees. As the tree gets larger the proportion of choice grades increases. A good many lumbermen are now cutting small trees at a profit, which figured against what they would make from the same trees in ten or twenty years means not profit, but loss. Some lumbermen are cutting small trees at a direct loss.* There is no more fruitful investigation for any lumberman than to figure from the cut of his own mill the volume and grades of lumber sawed from trees of different sizes.

The full use of standing timber.—The failure to cut fire-killed or otherwise damaged timber, to log inferior kinds along with the most valuable kinds, and the leaving of isolated patches which are hard to reach means an average loss to the owner of 1,000,000 to every 10,000,000 feet logged and often much more. It also means much greater danger from fire and insects, and a second growth poor in kind and quality.

Clean work in the woods.—Waste in the woods comes in part from leaving trees, which, though partly unsound or otherwise defective, are still merchantable. It comes in part from high stumps, from trees broken in falling and from lodged trees, from leaving timber in the tops and from failure to cut logs into lengths so as to provide for the fullest possible use of each tree. It comes in part from leaving in the woods, skid poles, ties, camp logs, and other timber used in temporary construction, instead of saving it for pulp, for lumber, or for use again. Especially after deep snow, scattered logs are often left lying in the woods, or even piled on the rollways. In the construction of logging roads and temporary buildings much waste occurs in the unnecessary use of timber of valuable kinds.

There are very few lumbermen in the United States who are not guilty of this waste in one or more forms. The remedy requires no detailed plan. It calls for thorough supervision, for the habit of thrift on the part of the operator, and the enforcement of thrift among his men. A logger who wastes timber in the woods for his employer should be sent out from them just as quickly as a wasteful edgerman or grader is sent out of the mill.

Economy in transportation.—In railroad logging unnecessary loss occurs in the failure to pick up logs fallen from cars or scattered by wrecks.

An average of probably 5 per cent of the timber put into streams for driving is lost. On long drives and rough streams a small part of this damage is unavoidable. But it can probably be reduced on the average by more than half by peeling and drying out logs of kinds which do not float well, by stream improvements, and by reasonable care on the drive itself.

ECONOMY IN THE MILL.

An average of more than one-third of the wood in the log is wasted in the mill. It is practicable, under present conditions, to reduce this nearly one-half. This means the use of thinner saws, of more bandsaws and resaws, and the disuse of gang saws. It means better machinery, more careful manufacture, and the sawing in round edge, or "waney" form of lumber which is worked over again before being finally used. It means the change of grading rules and market usage to admit random widths, odd lengths, and shorter and narrower pieces, and to allow defects which do not seriously reduce the value of the product for the use to which it is to be put. And it means fuller utilization of short boards, slabs, and waste.

MANUFACTURE OF BY-PRODUCTS.

Even when forest products are manufactured and used economically, great opportunity remains for the conversion of wood not utilized in logging or in the mill into useful by-products by chemical and other means. As timber becomes more valuable, we approach more nearly that complete utilization in which every part of the felled trees will be used.

If all the wood wasted in the manufacture of yellow-pine lumber in 1907 had been steam distilled for the production of wood turpentine, it would have yielded more than the total production of gum turpentine in that year. If all the wood wasted in the manufacture of lumber from spruce, hemlock, poplar, and cottonwood in 1907 had been used for paper making, it would have furnished all the paper made from wood in that year. If all the wood which went to waste in the manufacture of chestnut lumber in 1907 had been used to make tanning extract, we would have produced twice as much as was produced from the chestnut cord wood used for this purpose. The waste in the manufacture of beech, birch, and maple lumber in 1907 was nearly equal to the quantity of these woods cut for distillation. The waste in the manufacture of oak lumber was twice the quantity of all hardwoods used for distillation. These are some of the great examples of the failure to use wood fully.

PRESERVATIVE TREATMENT OF TIMBER.

Of all the wood in every form now in use in the United States, decay, fire, insects, and salt water borers destroy not less than the equivalent of 8,000,000,000 board feet each year. Of these, decay is far the most destructive. It is also the easiest to retard. The preservative treatment of timber will lengthen by ten to twenty years the life of woods now commonly used for posts, poles, ties, mine timbers, bridge timbers, and for much other construction work. It will also make profitable the use of many woods which, untreated, decay so quickly that they have little or no value. If preservative treatment makes the life of timber in use twice or three times that of untreated timber, only one-half or one-third as much timber is consumed by that use. Nor does this take into account that large saving in the labor of replacing decayed timber, which in the maintenance of railroad tracks, using untreated ties, is about one-third the cost of the new ties used each year, to keep the track in condition.

In 1907, 1,250,000,000 board feet of timber were treated, which was not more than one-quarter the quantity which could have been treated with profit to its users. There are about 700,000,000 ties in railroad tracks in the United States. They represent, untreated, an average cost per tie of about 12 cents a year. If all were treated the increase in their length of service would mean a saving of 2 3/10 cents per tie per year, or a total annual saving of about $16,000,000. More than $2,000,000 could be saved each year by treating all the poles, and nearly $2,000,000 if all the piling were treated. The saving in timber used in the mines would be about $12,000,000. If lumber so exposed in use that treatment is profitable were treated, the saving would not be less than $15,000,000. This means a total practicable saving of over $47,000,000 a year. It means also that the increased life given these timbers would make an annual saving in wood equivalent to 4,000,000,000 board feet, or 10 per cent of the yearly lumber cut.

Two preservatives are widely used in the United States. These are creosote and zinc chlorid. The chief advantage of creosote is that once injected into wood it prevents decay permanently. Its chief disadvantages are its cost and scarcity. Zinc chlorid is cheaper and an excellent antiseptic. But it will leach out if the treated wood is exposed to moisture.

A farmer can treat a fence post with creosote for about 10 cents and make it last twenty years. Apparatus costing from $50 to $75 will treat from 50 to 100 posts a day, depending upon the kind of timber. The butt of a 30-foot telephone pole can be treated for from 75 cents to $1. The plant will cost from a few hundred to several thousand dollars, depending upon its capacity. Piling properly treated with creosote is not attacked by salt-water borers. Mine timber can be treated with zinc chlorid for from $4 to $5 per thousand board feet. Ties can be thoroughly treated with zinc chlorid for 10 to 12 cents and creosoted for 20 to 30 cents.

USE OF SUBSTITUTES.

Seasoning and factory wastes can be reduced somewhat by improved methods of drying and manufacturing. But a larger part of the necessary saving in the use of timber must come through the substitution of other materials. Stone, brick, steel, and concrete are now less expensive building materials than wood, when depreciation and fire risks are taken into account. Steel is rapidly supplanting lumber in car construction, and concrete, steel, and masonry are taking its place in bridges. Savings possible in building and railway construction alone, if carried to the limit, would diminish by at least one-third the present consumption of lumber. In the furniture industry it is estimated that approximately 50 per cent of the beds now manufactured are made of metal. The use of pressed steel for desks, file cases, and other office furniture is becoming more and more common. To a small extent, as yet, steel is replacing wood for wagon axles, rims, hubs, and spokes, and in the form of thin plates is being used for paneling in wagon bodies.

TASK OF THE STATES.

The States in their relation to the forest face these specific duties: To adjust taxes on forest lands, so that they can be held profitably for forest purposes; to pass good laws for safeguarding forest property from fire, and enforce them; to conserve state forests and extend them to cover other forest lands needed for the permanent benefit of the whole State; and to cooperate with the Federal Government in teaching the people how to take care of their forests.

THROUGH BETTER TAX LAWS.

From now on the relation of taxation to the permanent usefulness of the forest will be vital. Present tax laws prevent reforestation on cut-over land and the perpetuation of existing forests by use. Laxity in their application and special exemptions supply no remedy.

Taxation of forest lands should be based either on the yield when cut or on the earning power of the forest. The former would mean a tax on the land alone, plus a tax on the timber when harvested; the latter would mean an annual tax on the capital value of the forest calculated upon the net returns expected from it. The tax on the timber when cut and an annual tax upon the land itself, exclusive of the timber, has practical advantages. It does not involve forecast of the rate of interest, of the risk of loss by fire, or of timber values, nor does it require exact statistics of the growth of timber.

A tax on the timber when cut and an annual tax upon the land itself, exclusive of the timber, is well adapted to the actual conditions of forest investment, and is practicable and certain. It would insure a permanent revenue from the forest in the aggregate far greater than is now collected, and yet be less burdensome upon the State and upon the owner. It is better from every side that forest land should yield a moderate tax permanently than that it should yield an excessive revenue temporarily, and then cease to yield at all.

THROUGH BETTER FIRE LAWS.

Forest fire laws are ineffective partly because they are wrongly framed, but mainly because they are not enforced. The purpose of forest fire laws is to prevent fires. That principle should obtain in enforcing as well as in drafting them. A fire law inflicting reasonable penalties which is enforced, is much more effective than a fire law inflicting excessive penalties which is loosely applied or waived.

Each State within whose boundaries forest fires are working grave injury, and that means every forest State, must face the fact squarely that to keep down fires needs not merely a law upon the statute books, but an effective force of men actually on the ground to patrol against fire. The man who puts out the most fires is the man who is looking for them, not the man who goes to a fire after it is under way. The system of voluntary fire wardens is good as far as it goes; but to make it really effective it must be combined with a force of trained men, whose first duty is fire patrol and who are sufficiently paid for their work.

STATE FORESTS.

In most States the area of forest land which will best serve the people of the State under state ownership and administration is much larger than the area now in state forests. In the extension of state forests, and in the better management of all state forest lands, the States face an immediate individual problem. Especially in the Lake States, vast areas of denuded lands, abandoned after logging destructive beyond all parallel, must be planted to trees long before they will even pay taxes.

EDUCATION.

The duty of teaching forest owners and users everywhere, how to conserve their forests, rests both with the Federal Government and with the States. The active cooperation of each State is essential. Many States present forest problems peculiar to themselves, which it is incumbent mainly upon each of them to solve. This can not be done without money, nor without trained men under a state forest organization.

THE NATION'S TASK.

The Federal Government, in its relation to the forest, faces two great tasks. The smaller is the conservation by use of forests which are already the property of the nation, or which it may acquire. The larger, in cooperation with the States, is to lead private owners to conserve by use four-fifths of the forests of the United States, which means to make forestry a household word and bring about universal household knowledge of its purpose, methods, and results. Forestry, through its relation to waterways and the wide shipment of its products, has special interstate relations.

ON PUBLIC FOREST LANDS.

In National Forests.—The forest lands which belong to the whole nation are in the National Forests, the Indian and military reservations, the national parks, and the unreserved public domain.

The National Forests conserve most of the water and one-third the timber of the West. This national heritage, whose resources so far as they can be measured in money are worth nearly two billions of dollars, is being rightly administered for the permanent use of the whole people.

At an average cost for protection of less than one-fifth of a cent per acre, the damage by fire on National Forests for the last three years has been, per million acres, about 3 per cent of that on private forest lands. In the same period the use of the National Forests by the people has more than doubled. In 1908 so great were the demands of the people's business that an average of only one-fifth of the time of the forest rangers could be given to fire patrol. This was the equivalent of all the time of one man for the patrol of 580,000 acres, an area half the size of the State of Delaware.

The quantity of mature timber taken from the National Forests each year could be increased several times with safety to the forest and with benefit to the people. But if the forest logged is to yield a good second crop, 20 to 30 cents must be spent for every thousand board feet harvested, in marking the trees to be cut, in supervising the logging, and in burning, as a safeguard against fire, the brush left upon the ground. If funds are provided to meet the growth of National Forest business, the safety of the forests will not be endangered nor will their increase year by year in national usefulness be checked. If these funds are withheld, either the National Forests must be inadequately protected or inadequately used. The least important of the great functions of the National Forests is to furnish revenues. It would be bad business management no less than shortsighted public policy to let any part of the property of the people lack the funds for operating expenses needed to make it yield its full return. But the use of the National Forests by the people, great as it is already, has only begun. It will increase as fast as adequate means are provided.

In national parks and Indian and military reservations.—National parks, Indian reservations, and military reservations contain a total of 13,000,000 acres of forest land, and more than 45,000,000,000 board feet of timber. Their location with reference to the National Forests makes cooperation in handling them an obvious and essential step.

The cooperation of the Department of Agriculture with the Department of the Interior in the handling of forest lands in Indian reservations is good in plan and purpose, and effective so far as funds are available; but for lack of money the larger area of forest lands in Indian reservations is neither being protected from fire nor conservatively used.

The forest lands in national parks and military reservations, as well as in Indian reservations, subject to the specific purposes for which they are held, should be administered under the policy and methods which obtain on National Forests, and adequate funds should be provided for the work.

It is no less the duty of the nation to take good care of all its forests than it is the duty of the private owner to conserve his forest holdings.

On forest lands of the unreserved public domain.—The timber and stone act has been in force thirty years. It has brought about for $30,000,000 the sale of timber worth at a very conservative estimate over $300,000,000. The number of entries is 88,000, and they cover a total of nearly 12,000,000 acres. The Federal Government, as the steward of the people, is losing yearly about $25,000,000 of the actual value of timber still being disposed of under this act, as well as the title to 1,500,000 acres of land which should be kept permanently as the property of the nation. The timber and stone act should be repealed, not only because of these facts, but also because it does not serve any useful public purpose. With its repeal there is urgent need for the sale of mature timber at its actual value and under proper restrictions, from unreserved public lands, both for the use of settlers and to supply the general need.

By consolidation of holdings.—Several western railroads own, as land grants, the odd-numbered sections in many National Forests. Legislation is urgently needed to permit the Federal Government to acquire these sections and other interior private holdings by exchanging for them timber inside the Forests or land of equal value outside, so far as practicable in compact bodies. Until such exchanges are made the protection and use of National Forests cut up by land grants or other large private holdings will continue to be expensive and difficult.

In the Appalachian forests.—Studies made at the direction of the congress show that the purchase for conservation by use of mountain forests in the southern Appalachians and in the White Mountains is an immediate national duty. Every acre in these proposed National Forests is on the watershed of navigable streams, most of which carry interstate commerce. These watersheds are already partly denuded and the process is going steadily and rapidly forward. The millions spent by the Government in dredging silt from the streams which flow from these mountain forests is insignificant in comparison with what must be spent unless the cause is dealt with, as well as the effect. Observation and record both show that the frequency and duration of floods in many of these streams is increasing. The flood damage in one year was more than it would have cost the Federal Government to buy in that year these eastern mountain forests, whose conservation is essential to the material welfare of the people of the East. The purchase by the Federal Government of all the mountain forest lands in the southern Appalachians and in the White Mountains is neither necessary nor advisable. The purchase of not more than 10 per cent of their total area upon the watersheds of important streams and the cooperation of the Federal Government in the conservation of adjacent forest lands owned by the State or privately would get adequate results.

Delay has entailed enormous preventable damage to forests and farms in the Appalachian and White Mountain regions, to their developed water powers, and to their vast water powers not yet developed. If delay continues, the damage will be irreparable.

COOPERATION WITH STATES.

The Federal Government has made forest studies in cooperation with ten States. These studies have aided in sound forest legislation, in a better handling of state forest lands, and in a better understanding by the people of the State of the need for forest conservation. This fruitful cooperation, in which the Federal Government bears, and rightly bears, one-half the cost, should be available to all other States. The money spent upon it is not merely an admirable national investment, but it maintains the principle of active cooperation between State and nation, vital to the right working out of our national forest problem.

EDUCATION.

The right use by American citizens of the forest and of timber will not be general until they learn how to practice forestry. For ten years the Department of Agriculture, by spreading broadcast the facts gained in its forest studies and by actual cooperation with the individual in the handling of his timber tract, his woodlot, his forest plantation, and his timber-treating plant, has carried forward a national campaign in education. One great result is the awakening of the American people to their national and individual need for forest conservation. The other is the conservative management of private forest lands of small area relatively, but of great value as object lessons.

Forestry has been given root and being in the great body of American citizenship. No country takes poorer care of its private forests than ours, and no nation has a more wholesome and enthusiastic public sentiment for the right use of the forest than our own. The basis already exists upon which to build a structure of forest conservation which will endure. But for this is needed the definite commitment of the Federal Government to its inherent duty of teaching the people how to care for their forests. Neither private enterprise unaided nor state enterprise unaided will achieve this result soon enough.

So far as practicable and within reasonable limits the forest studies made by the Department of Agriculture should be paid for by the industries and individuals whom they directly benefit. But the final responsibility for investigative work in forestry, which otherwise could not be done effectively or done soon, rests upon the Federal Government.

WHERE WE MIGHT STAND.

By reasonable thrift we can produce a constant timber supply beyond our present need, and with it conserve the usefulness of our streams for irrigation, water supply, navigation, and power.

Under right management our forests will yield over four times as much as now. We can reduce waste in the woods and in the mill at least one-third, with present as well as future profit. We can perpetuate the naval-stores industry. Preservative treatment will reduce by one-fifth the quantity of timber used in the water or in the ground. We can practically stop forest fires at a total yearly cost of one-fifth the value of the standing timber burned each year.

We shall suffer for timber to meet our needs until our forests have had time to grow again. But if we act vigorously and at once we shall escape permanent timber scarcity.

We take out of our forests each year three and a half times as much wood as they grow, partly because we waste more wood than any other nation. The saving of wood practicable in logging, in the mill, and in use has already been pointed out, but we fail to produce each year much more than the wood we need because we misuse the forest.

Against an average yearly growth of 12 cubic feet per acre in the United States, the forests in Germany, all of which are rightly handled, yield each year 48 cubic feet per acre, and their most common trees do not grow naturally as fast as ours. It is certain that the average annual yield of forests in this country can be made, through protection from fire and through conservative logging, much larger than that of forests in Germany.

Every owner of forest lands can stop fires and log conservatively, with immediate profit, as well as with permanent profit.

Most other countries have already learned that the forests which are not conserved will be used up, and they are taking care of what they have. We are among the last to learn it. We can profit by that knowledge if we will. But if we will it means action united, vigorous and prompt, State and nation.

SOURCES OF MATERIAL.

The estimates which this summary contains are based on all information about our forests possessed by the Federal Government and upon vigorous work for about six months in the special field of inquiry before the section of forests of the National Conservation Commission. One feature of the latter has been the sending out of more than 100,000 requests for information to forest owners and forest users throughout the United States.

The inventory made by the section of forests, simply because its scope has been wider than that of any other inventory of our forests, has shown still more clearly the urgent need for exact knowledge of just where we stand. We must have as a working basis a careful census of the kind, quality, and quantity of standing timber in the United States, of the condition of our forests, and of the wood we use for all important purposes. The nation can no more invite the best use of a national resource unless it knows essentially what that resource is than can the individual direct his own business successfully without taking careful stock of what he has.

The compilation of the data upon which this summary is based would have been impossible had it not been for the vigorous cooperation of state and federal agencies concerned, as well as of organizations representing national industries dependent wholly or mainly upon the forest. Had it not been for the cooperation of the Bureau of the Census, the voluminous and detailed computation necessary to the statement of the final results could not have been made in time; had it not been for the cooperation of the Bureau of Corporations we should not possess a trustworthy estimate of the aggregate amount of standing timber in the United States; and to the United States Geological Survey and to Mr. Bailey Willis, geologist and engineer, is due the scientific and comprehensive statement of fact as to the relation of the forests to the stream. These and many other agencies, federal, state, and private, have provided the material upon which this summary is based.

Both in the preparation of this summary and throughout the work preliminary to it I have been associated with Mr. R. S. Kellogg and Mr. W. T. Cox, of the Forest Service, who were designated for this task by the Forester. Their individual share in several important phases of the work greatly exceeds my own.

Through the compilation of material relating to forests and forestry, the following members of the Forest Service have aided greatly in the work: Messrs. W. Bradfield, H. S. Bristol, E. E. Carter, E. H. Clapp, T. C. Cleveland, jr., M. Cline, C. S. Chapman, S. T. Dana, E. H. Frothingham, W. B. Greeley, W. L. Hall, L. F. Hawley, G. M. Homans, C. Leavitt, L. Margolin, A. B. Patterson, A. S. Peck, J. G. Peters, A. C. Ringland, H. S. Sackett, W. F. Sherfesee, H. A. Smith, G. B. Sudworth, H. F. Weiss, P. P. Wells, E. A. Zeigler, and R. Zon.

Valuable assistance in the compilation of data has also been rendered by Prof. Henry S. Graves, director of the Yale Forest School, and a member of the National Conservation Commission; by Prof. Filibert Roth, in charge of instruction in forestry at the University of Michigan, and by Prof. F. R. Fairchild, assistant professor of economics in Yale University. Through general supervision of the methods for securing statistical data relating to forests and of the form of its final presentation, as well as in the aid throughout the work of his wide knowledge and experience, Mr. Henry Gannett has helped greatly to make the compilation what it is.

OVERTON W. PRICE,
Secretary, Section of Forests.

LANDS.

THE NATIONAL ESTATE.

The land area of the United States, excluding Alaska and the insular possessions, is about 3,000,000 square miles, or 1,920,000,000 acres. Of this area over half is arable, and a little less than half is occupied as farm land. About one-fourth is forest and one-eighth sparse wood land and cut-over land. Two-fifths is arid or semiarid, generally requiring irrigation; one twenty-fifth is swamp and overflow land requiring drainage. Most of the dry, wet, and sparsely wooded lands, with part of the forest area, is adapted to grazing.

About two-thirds of the land has passed into private holdings. Of the original 1,920,000,000 acres there remained July 1, 1908, 387,000,000 acres open to entry; nearly all of this is arid or otherwise unsuitable for settlement by families. There are also about 235,000,000 acres in national forests, national parks, and other lands reserved for public use.

USE AND ABUSE OF LANDS.

AGRICULTURAL INDUSTRIES.

In 1900 the farm lands comprised 838,591,774 acres; there were 5,737,372 farms, averaging 146.2 acres each. Of the farm lands, 414,419,487 acres, or 50 per cent of the farm area and 21.6 per cent of the total land area of the country, were improved. The value of the farms was $20,439,901,164, or 23 per cent of the wealth of the country. Of this value, 81.3 per cent was in lands and buildings, 15 per cent in live stock, and 3.7 per cent in implements and machinery.

The value of farm products in 1900 was $4,717,069,973, or $822 per farm, yielding a gross return of 23 per cent on the capital. Since 1900 agricultural production and investment have increased greatly, though exact figures are lacking.

In 1900, 10,381,765 persons, or 35.7 per cent of the wage-earners of the country, were engaged in agriculture. The proportion of the population so occupied is decreasing; in 1880 it was 48.3 per cent. The use of farm machinery is increasing rapidly.

We grow four-fifths of the corn crop, three-fifths of the cotton-crop, and one-fifth of the wheat crop of the world. We plant about 100,000,000 acres of corn, yielding an average of 25 bushels per acre; nearly 50,000,000 acres of wheat, averaging about 14 bushels; and 30,000,000 acres of cotton, yielding about 12,000,000 bales.

We had on January 1, 1908, 71,000,000 cattle, worth about $1,250,000,000; 56,000,000 swine, worth $339,000,000; and 54,000,000 sheep, worth $211,000,000. In 1900 we had $137,000,000 worth of poultry, which in 1889 produced 293,000,000 dozen eggs.

PRODUCTIVITY OF THE SOIL.

Over one-third of our wage-earners are engaged in agriculture, and all our people depend for their chief food supply on the productivity of the soil. The productivity is conveniently measured by crop yield.

Our crop yield per acre, according to the last three censuses, has been as follows:

Yield per acre.

		1899.	1889.	1879.
Barley	bushels..	26.8	24.3	22.0
Corn	do....	28.1	29.4	28.1
Oats	do....	21.9	28.6	25.3
Rye	do....	12.4	18.1	10.8
Wheat	do....	12.5	13.9	13.0
Rice	pounds..	807.0	797.0	632.0
Hay	tons..	1.4	1.3	1.1
Potatoes	bushels..	93.0	83.6	96.7

The yield estimated by the Bureau of Statistics of the Department of Agriculture for forty years, grouped by averaging ten-year periods (in order to eliminate the effect of exceptional years), is as follows:

Yield per acre.

		1867-1876.	1877-1886.	1887-1896.	1897-1906.
Corn	bushels..	26.2	21.1	24.0	25.4
Wheat	do....	12.0	12.5	12.7	13.8
Oats	do....	27.5	27.8	25.5	30.1
Barley	do....	22.8	22.4	22.7	25.5
Rye	do....	13.6	13.0	12.9	15.7
Buckwheat	do....	17.6	14.5	15.3	18.1
Hay	tons..	1.22	1.24	1.20	1.43
Potatoes	bushels..	90.0	82.0	75.0	86.0
Cotton	pounds..	181.0	170.0	172.0	191.0

Of these figures, those taken from the census are the more accurate, those taken from the Bureau of Statistics the more fairly representative of trend. They show that on the whole our crop yields are not decreasing; especially during the last ten years they have increased.

Grouped by States, the figures (appended among the accompanying papers) show for the older States an increase in yield throughout the forty years; and for the States in an early stage of settlement at the beginning of the record they show the influence of relatively large yields from virgin soil, followed first by a reduction and later by an increase of yield with improvement in agricultural methods.

The foregoing figures were supplemented by information obtained directly from every county in the United States. A schedule of inquiries was sent to a large number of farmers asking them whether in their judgment the fertility of the soil in their neighborhood was maintained, and, if so, whether by means of fertilizers or crop rotation, or both. The answers, to the number of about 30,000, are in accord with the foregoing figures. In the northeastern States little land is impoverished; in most counties none was reported. In the southeastern States the impoverishment is greater, though, except in West Virginia and Georgia, the proportion is not large. In the southern central States, excepting Alabama, Kentucky, and Tennessee, the proportion of impoverishment is large; while in the northern central States, excepting North Dakota, Nebraska, and Kansas, the proportion is small. In the western portion of the country there is a wide range, five States reporting no reduction in productivity, two reporting a small proportion, and four a considerable proportion. The total area of the counties comprising impoverished land is 307,730 square miles, or 10.3 per cent of the land area of the United States.

Local diminution in productivity is traceable to different causes:

1. The chief cause is erosion, including both leaching and washing of the soil. The annual loss due to this cause has been estimated at 7 to 10 per cent on upland farms, or some $500,000,000 yearly for the country. It can be largely or wholly prevented by proper cultivation and selection of crops.

2. A potent cause is continuous cropping, coupled with injudicious seeding. It can be counteracted by rotation of crops, selection of seed, and use of fertilizer.

3. A frequent cause of diminished yield is ravage of growing or ripening crops by insects, or sometimes by mammals. It can be remedied by the application of modern scientific methods.

That diminution in productivity is unnecessary is shown clearly by comparing our crop yields with those of long-settled and densely populated countries, in which the farming is more careful. The following figures show that our yields of oats, barley, and rye are much below, and our yield of wheat below half, those of Germany and the United Kingdom:

Average yield per acre, 1897–1906.

Country.	Wheat.	Oats.	Barley.	Rye.
United States	13.8	30.1	25.5	15.7
Germany	28.0	47.4	33.5	24.2
Austria	17.8	27.2	22.9	17.6
Hungary	17.6	30.[illegible]	22.7	17.3
France	19.8	27.8	22.4	16.7
United Kingdom	32.2	44.6	34.3	26.2

Both the American and European figures showing crop yield are in accord with fundamental principles. It is the natural law of soil to increase in fertility when properly treated. In a state of nature plants spread over rocky or earthy surfaces and combine with the action of the elements in disintegrating the material; the humus and other acids of plant growth and decay decompose the inorganic substances and dissolve the earth salts, rendering them available for plant food, and unless the slopes are excessive the material is in time reduced to a rich soil supporting an abundant flora. When such a soil is brought under cultivation it may by suitable treatment, including selection and rotation of crops, cultivation, drainage or irrigation, and other means, be made to continue increasing in richness and productivity; and in most cases the increase may be aided by judicious mulching and fertilizing.

The value of commercial fertilizer used in the United States is increasing; in 1880 it was $0.10, in 1890, $0.11, and in 1900, $0.13, per improved acre.

In conformity with these figures and principles, the largest yields of cereal crops are in the northeastern States, where intensive cultivation has been made necessary by dense population and consequent scarcity of land, and in the arid regions, where careful selection and cultivation have been induced by scarcity of water.

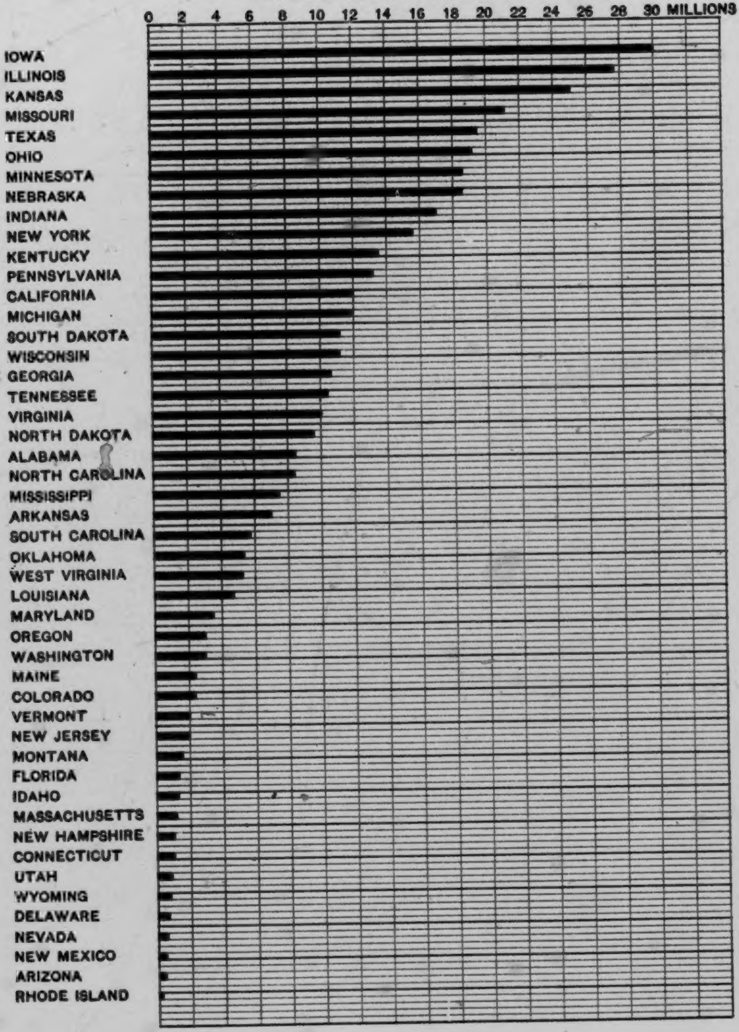
The figures for our crop yield since 1868 show a notable increase during some ten years past which can hardly be ascribed to the growth of intensive culture alone. It seems fair to credit this increase chiefly to the general improvement in farming due to the acquisition and diffusion of definite information by the Department of Agriculture, in conjunction with the experiment stations, state agricultural departments, agricultural colleges, and other scientific agencies. In connection with improved knowledge, the introduction of seeds and plants adapted to special conditions of soil and climate and the eradication of insect enemies have been important factors in maintaining and increasing production.

ABANDONED FARMS.

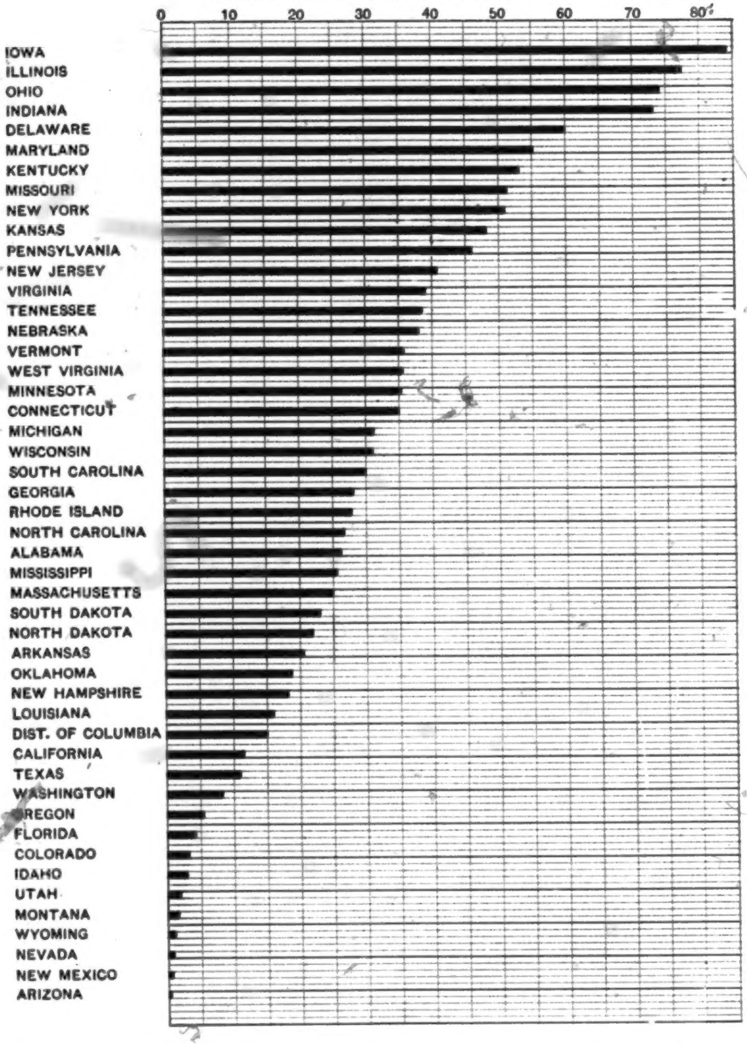
The schedule of inquiries addressed to the farmers in all the counties of the United States included questions as to the extent of abandoned farms. The 30,000 replies tabulated show that 16,597 square miles of farm land, or 0.6 per cent of the total area of the country, have been abandoned, and that 6,076 square miles, or 0.2 per cent of our territory, were, after abandonment, devastated by soil erosion.

Half of the abandoned lands are in southeastern United States. A few years ago abandoned farms were common in New England; of late they are largely reoccupied and rendered productive mainly by Italian or French-Canadian farmers.

Neither the abandonment of farms nor the local impoverishment of fields can justly be ascribed to deterioration of the soil; like our low crop yields, they are due to general industrial and economic conditions, which are not only susceptible of control, but are steadily changing with increasing density of population. In most rural districts, land is cheap and abundant, and labor costly; and the chief efforts of farmers are directed toward getting the largest returns per unit of labor rather than per unit of land. Especially in newly settled areas, farming is hasty and careless; the same crops are grown year after year until they run out; no attention is given to soil wash or to the maintenance of friability by drainage or otherwise, and little to the selection of seed; while fertilizing and mulching are neglected. In its legitimate use, the soil is abused to the limit. The condition is due partly to ignorance and cupidity, though chiefly to inadequate transportation facilities. With increasing population, markets are brought nearer to the farms, and traffic is facilitated; then, as in some of the northeastern and southern States, intensive or at least careful cultivation is adopted, and generally within a few seasons the productivity is raised even above that of the virgin soil.



ACREAGE OF IMPROVED LAND IN 1900.



PERCENTAGE OF IMPROVED LAND TO TOTAL AREA.

In districts liable to extensive soil erosion, the abandonment of fields is disastrous; in some cases the old-field erosion not only removes the soil proper, but carries away the subsoil and even the superficial deposits, exposing bare rocks or intractable formations over which soils naturally redevelop with extreme slowness, and can not be extended artificially except at large cost. The fact that over 6,076 square miles, or 3,888,640 acres, of our abandoned fields have been destroyed in this way is appalling. Not only would the area form nearly 100,000 farms capable of sustaining a population exceeding that of any one of our 12 least populous States, but each gully starts others in such manner as continually to extend the devastation. The evil should be remedied without delay. Communities and States should be awakened to the sacrifice of public interest through old-field erosion. First in connection with abandoned fields, and progressively in cultivated fields, soil wash should be considered a public nuisance, and the holder of the land on which it is permitted to occur should be held liable for resulting damages to neighboring lands and streams.

NECESSITY FOR INCREASING CROPS.

The population of the United States in 1900 was 76,303,387; probably it will double by the middle and triple before the end of the present century. In view of this growth, the question of food supply assumes the highest importance. How shall the greatly augmented demand for foodstuffs be met? Can sufficient food be obtained from our own soil or will it become necessary to import, and, if we import, how shall we find the means?

Hitherto we have not only supplied ourselves with foodstuffs, but have had a small (and decreasing) surplus for export. They were in the last census year produced from 647,666 square miles of farm land, or 21.6 per cent of the total land area of the country. To supply the needs of our prospective population at the end of the present century by merely increasing the area of farm land would require that nearly two-thirds of our entire area be under cultivation—or far more than our aggregate arable lands, since arid districts, rugged country, and mountainous areas too elevated to produce crops form half the area of the United States. Even during recent decades the increase in cultivated land has not kept pace with that of population. Between 1890 and 1900 the population increased at the rate of 20.7 per cent, while the area of improved land increased only 15.9 per cent; and, as cultivation crowds on cultivability, the difference must widen.

Aside from the importation of foodstuffs, but one feasible way of meeting our growing demand appears—i. e., to increase our crop yields. That this is not only feasible but entirely practicable is shown by the larger yields of long-settled countries, by the reclamation of abandoned farms with increasing local population, by the general increase in our crop yield during the last decade, and by the natural tendency of soils to increase in fertility when properly treated.

There is some diversity of opinion among experts as to the trend of our crop yield and as to the reasons for increase or decrease. Early in 1908 there was a decided opinion (expressed at the governors' conference and elsewhere) that our yield began to decline soon after the breaking up of the virgin soil and has continued to decline throughout the country, but the exhaustive figures brought together, largely by Victor H. Olmsted, Chief of the Bureau of Statistics, Department of Agriculture, and appended among the accompanying papers, render it fairly clear that the minimum is already past and that the normal increase in productivity has begun. Thus far the increase is slight and does not at all keep pace with the growth in population. The conditions affecting productivity are discussed by Professor Whitney, Chief of the Bureau of Soils; Doctor Galloway, Chief of the Bureau of Plant Industry, and other specialists in accompanying papers.

DECLINE IN EXPORTS OF FOODSTUFFS.

During the last ten years our exports of foodstuffs have diminished relatively as compared with the preceding decade, suggesting that we are consuming more and more of our product. This may represent a temporary oscillation, like several in the past; it may be due in part to inadequate transportation facilities, such as prevented the satisfactory movement of the harvests of 1906; but it probably marks the beginning of the end of our exportation of foodstuffs.

The proportion of our wheat crop exported yearly as wheat and flour since 1871 has ranged about from 8 to over 41 per cent; the fluctuations being traceable to variations in size of crop coupled with the increasing home demand. The home consumption per capita since 1871 has ranged from 3.44 to 7.07 bushels, averaging about 5 bushels, with a tendency to increase. The percentages of exports to total crops, averaged by groups of years, have been: 1871–1877, 23.3 per cent; 1879–1887, 31.17 per cent; 1888–1897, 30.45 per cent; and 1898–1907, 27.18 per cent. From the first to the second of these groups there was a decided increase in the proportion of exports; the period was one of rapid extension of settlement in wheat-growing districts. In the second and third groups the proportion was practically the same, though the extension of settlement continued. The fourth group shows a decline, and the last four years a great decline, not only in the proportion but in the absolute volume of exports.

Exports of other cereals are too small and too irregular in amount for useful discussion.

The amount of meat produced annually is not recorded, but the number and value of live stock are estimated annually by the Department of Agriculture, while the live stock and meat exports are recorded. When the values of such exports are compared with those of live stock, the figures show a marked decline in foreign shipments during the last decade. The figures are in accord with those for wheat and flour.

Both classes of exports seem to show that the country is past the period of maximum proportional exportation of foodstuffs, and that hereafter the proportion will continue to decrease as the demands of our industrial population gain on our agricultural production. This conclusion is fortified by the values of our exports of all crude foodstuffs and food animals, which has fallen from $305,000,000 in 1898 (the largest in our history) to $167,000,000 in 1907, with an average of $151,000,000 for the six years 1902–1907, inclusive.

The record of exports is consistent with the fact that in no case is the production of our food crops increasing so rapidly as our population. In the decade between 1890 and 1900 the increase of population was 20.7 per cent; the increase in production was 19 per cent for corn, 15 per cent for wheat, and 7 per cent for oats, potatoes making no appreciable gain. The increase in live stock is more marked, though it averages less than the gain in population; during the same decade cattle increased 23 per cent and sheep 24 per cent, while swine increased only 5 per cent.

WASTES DUE TO NOXIOUS INSECTS AND MAMMALS.

Aside from careless or ignorant farming and such hostile climatic conditions as storms and droughts, the most serious enemies to crops are noxious insects and mammals.

The chief insect enemies of the grains are the corn-root worm, the bollworm, the chinch bug, the Hessian fly, plant lice, grasshoppers, cutworms, and army worms. The worst enemy of cotton is the boll weevil. Fruits are injured chiefly by the codling moth and the San Jose scale. The Bureau of Entomology estimates that the annual damage by noxious insects to growing crops, fruit trees, and grain in storage is no less than $659,000,000. This total includes the cost of preventive measures which greatly reduce the aggregate loss.

The average yearly loss to animal products from flies, ticks, and other insects is estimated at $267,000,000. This does not include the enormous loss of human life and the cost of disease due to house flies, mosquitoes, fleas, and other germ-carrying insects—a loss much greater than that suffered by the live stock and their products.

The Biological Survey estimates that the damage to live stock and crops by wolves, rats, mice, and other mammals averages over $100,000,000 yearly. This figure also includes the cost of preventive measures; without them the losses would be much greater. Birds generally are beneficial as destroyers of noxious insects and mammals.

While the figures are staggering in the aggregate, they represent careful and frequently repeated estimates by conservative specialists, and in each case they are in accord with the common observation of intelligent farmers and other citizens. They must be regarded as trustworthy and as representing an enormous preventable waste.

LOSSES OF LIVE STOCK BY DISEASE.

The appended statement by the Bureau of Statistics of the Department of Agriculture shows that the average loss by disease during the past five years was: Among horses, 1.8 per cent; among cattle, 2 per cent; among sheep, 2.2 per cent, and among swine, 5.1 per cent. The aggregate annual loss averaged $93,000,000.

The most prevalent disease among cattle and swine is tuberculosis; it is estimated that at least 1 per cent of beef cattle, 10 per cent of dairy kine, and 2 per cent of swine are affected. Sheep and cattle suffer seriously from scabies, while hog cholera is prevalent among swine. Texas fever among cattle (transmitted by a tick) is a destructive disease, causing a direct annual loss estimated at $40,000,000. All these diseases are remediable, and some or all may be eradicable.

The total annual losses to the agriculture of the country, including live stock, animal products, and grain in storage, from insects, mammals, and disease is estimated at $1,142,000,000, or one-sixth of the total production.

WILD GAME AND FUR-BEARING ANIMALS.

Our wild game and fur-bearing animals have been largely exterminated. One of the most painful chapters in the period of our wanton waste is the destruction of wild game. Everyone knows the story of the passing of the buffalo and of the fur seal; not so well known is the recent history of the moose, caribou, deer, elk, antelope, mountain sheep, and mountain goat. A generation ago most of these abounded on the western plains and mountains; now they are rarely seen. Fortunately, before their complete extermination, most of the States and the United States began their protection, and under wise laws, generally well enforced, many of the game animals are now increasing.

With protection the game animals, like many fish and game birds, are becoming a source of large benefit to the country, as is well shown in the appended statement by Dr. C. Hart Merriam, Chief of the Biological Survey.

With game birds the story is much the same—wanton destruction until the number was greatly reduced, followed in recent years by wise protection, allowing the remnant to survive and even to increase.

Our game animals and birds supply food, skins, furs, and feathers to the annual value of several million dollars, and the amount is increasing.

FISH.

Our fish supply is now largely dependent on artificial propagation. The annual value of the fisheries of the United States is $57,000,000; the products form an important element of our food supply. Salmon, trout, shad, lobsters, and other important varieties are maintained almost exclusively by propagation and restocking.

The production and propagation of fish and the restocking of streams and lakes are seriously retarded by conflicting laws or absence of laws in the different States; in some cases, as in Columbia River, the diversity of state laws is seriously inimical to the maintenance of the fisheries. It is of the utmost importance that the States should cooperate among each other and with the Federal Government for the protection and development of the fish and fisheries of interstate streams and lakes.

THE OPEN RANGE.

The area of open range on the Great Plains, in the Rocky Mountains and in the Great Basin exceeds 300,000,000 acres. The climate ranges from temperate to hot and from semiarid to desert. The pasturage was originally variable in quality, though generally sparse. The greater part was excessively overstocked soon after settlement began, and in some districts the pasturage was virtually destroyed. On the whole the range is in bad condition and of greatly reduced value; the portions occupied by sheep are especially poor, owing to overstocking and trampling.

It is clear that the public range is greatly deteriorated and that the deterioration is still in progress. It is equally clear that it might be restored by proper regulation of grazing, coupled in some cases with complete protection for terms of years, perhaps with some reseeding. The requisite control can be exercised only by the owner of the range, the Federal Government. Experts are of opinion that in most cases restoration can best be accomplished by leasing to stock owners for considerable periods, and allowing them to fence their holdings; for under such a system the stockmen would be interested in maintaining and improving the pasturage, while the governmental cooperation would afford protection from lawless invasion by competitors. The same system would alleviate the shocking cruelty of the range, under which stock have been starved and frozen and slaughtered by thousands through the shortsight and cupidity of stockmen having no interest in range or State beyond that of skinning it to the utmost for immediate profit.

SWAMP AND OVERFLOW LANDS.

The area of swamp and overflow lands is estimated at 75,000,000 or 80,000,000 acres, or about 4 per cent of our territory. The swamp-land area is capable of fairly exact delimitation and has been generally mapped, while the land subject to overflow can not be sharply defined, and the statements of area are merely approximate.

The swamp-land act of 1850 granted to the States then in existence all the lands within their limits classed by the surveyors of the General Land Office as swamp. Under this act 65,582,503 acres have been patented to the States; while 1,307,700 acres, nearly all in Minnesota, remain in public possession.

Of the swamp lands patented to the States, 60,142,003 acres have been conveyed to individuals or companies, leaving in possession of the States 5,440,500 acres.

In the States not affected by the swamp-land act the greater part of the wet lands have apparently passed into private ownership, except in those admitted since 1850, to which it has been judicially decided that the act does not apply and in which the swamps are inconsiderable, the United States still retains the greater share.

The cost of reclaiming swamp and overflow lands varies widely. Generally it is estimated that the value of the reclaimed lands is double or triple the original value plus the cost of reclamation. Practically all the wet lands of the country can be reclaimed at profit, and it is estimated that they would form homes for a population of 10,000,000. The chief obstacle is lack of coordination; generally the work can not be done by settlers or pioneer families, or even by communities, since reclamation projects are necessarily extensive and costly, and in many cases cross state boundaries. The plan of the Inland Waterways Commission contemplates reclamation of swamps and requisite protection of overflow lands as a part of a general system of improvement designed for the control and utilization of the waters. The plan is feasible, and when carried out will doubtless benefit the country greatly through increasing the capacity for population and production and converting the present wastes into sources of wealth.

The reclamation of swamp and overflow lands is in progress in several sections, usually under state appropriations, sometimes by county authorities or drainage districts. Details appear in appended papers prepared in the Geological Survey and in the Office of Experiment Stations.

A large incidental benefit arising from the drainage of swamp and overflow lands is the reduction of malarial and other disorders and the increase in viability and efficiency of our population. This aspect of the reclamation is discussed by Prof. Irving Fisher in the appended paper on "Conservation of life and health."

INCREASE IN PRIVATE HOLDINGS.

About five-sixths of the land area of the United States has passed into private holdings. In the early history of the country there were extensive land grants, most of which were gradually subdivided with settlement.

The land laws of the United States were framed with a view to the settlement of the country and the making of homes, and during the greater part of our history this policy was pursued by both nation and settlers. During recent decades, especially since forests, minerals, waters, and in some cases pasturage, came to be recognized as valuable in themselves apart from the land surface, individuals and corporations have frequently taken advantage of opportunities to acquire large holdings of land in order to gain control of the associated resources, and in many instances energetic farmers and other owners have acquired large tracts of land for agricultural purposes. The question of land holding is fundamental to the policy and practice of our Government, and it would seem of the greatest importance to ascertain whether the current tendency is toward large holdings with consequent landlordism, or toward smaller subdivisions and freehold homesteads. Naturally the tendency can be ascertained only through the facts of private ownership in the several sections of the country.

With a view to gaining the best information available, a schedule of inquiries was sent out in large numbers to selected farmers residing in every county of the United States; and, while the inquiries were designed to elicit information on other subjects, several were directed to the question of increase or decrease in area of holdings. When the 30,000 useful replies, averaging about 10 from each county, were classified by counties, it was found to be the opinion of the correspondents that in 48 per cent of our area the size of farm holdings is increasing, and that in the remaining 52 per cent the size is either decreasing or there is no appreciable change.

The States in which the majority of the farm holdings were reported as increasing are mainly those west of the Mississippi, with a few farther eastward. Thus it appears that the tendency toward increase is greatest in newly settled regions, and that in the long-settled sections the average holdings either remain unchanged or tend to decrease.

In the holdings of mineral lands there is a marked tendency toward increase in area. This is decided in the case of iron lands, and is of course connected with the greater economy of large operations in mining, transporting, smelting, and manufacturing. In oil lands the tendency toward consolidation is apparently slight; in coal lands and those containing other minerals the tendency toward increase is intermediate.

In timber lands the tendency toward consolidation is strong, and has gone far toward placing control of such lands in a few hands. It appears that the monopolization is partly in the interests of economy in logging, milling, and manufacturing, but chiefly speculative.

On the whole there is a distinct tendency toward increase in size of holdings, chiefly in nonagricultural lands, but it is not so decided as to indicate that the homestead policy is unsatisfactory to the American people or out of accord with public welfare.

THE PUBLIC LANDS.

DATA AND POLICY.

The inquiry concerning the public lands involved a continuation of the work of the Public Lands Commission appointed by the President October 22, 1903. The information compiled by that commission has been utilized with such amplification or modification as seems justified by the added experience of three years, and the further knowledge obtained by the government bureaus directly in touch with public-land questions, viz., the General Land Office, the Geological Survey, the Reclamation Service, the Forest Service, and the Indian Office.

So far as the lands owned by the United States are concerned, the effort has been to determine the true relation of the public-land laws, as they are and as they should be, to the fundamental conditions affecting the permanent efficiency of the people. The former is mainly founded on the following premises:

1. The nation should hold in its possesion and maintain in efficient condition those areas which are less valuable for agricultural use or home making than for conserving unique natural beauty and wonders, the water supply, and the timber.

2. The resources still belonging directly to the nation which must necessarily be diminished and finally destroyed by use, should be exploited and used in a way to return the greatest benefit in the long run to the greatest number, the essential caution being to prevent waste, and, without prohibiting or hindering economical development, to prevent such monopoly as might artificially increase the cost of the resources to the people beyond what would bring to the exploiter a full reasonable profit and no more.

3. When the land itself, independent of the minerals under its surface, is more valuable for agricultural use than for permanent dedication to the public use, it should be conveyed in such areas as will furnish a reasonable living to an average family to those who will actually make homes on it, and to no others.

4. Pending the disposal of any public land by reservation for public use, or by appropriation under the public-land laws, it should be protected from deterioration and so administered as to serve the best interests of all the people.

These conditions can not be met certainly without a classification of the public lands.

LAND DISPOSAL.

On July 1, 1908, there were about 755,000,000 acres of public lands neither appropriated nor reserved, including approximately 368,000,000 acres in Alaska and 387,000,000 acres in mainland United States. Between June 30, 1904, and June 30, 1908, the unappropriated and unreserved area of mainland United States was reduced from 473,836,402 acres to 386,873,787 acres.

The problem of dealing with the remaining public land is the more difficult and important because the choice lands for farming are gone. There is great pressure for disposing of the remaining public land in larger homesteads on the plea that, since it is of less efficiency, a family will need more to make a reasonably comfortable living. Yet, although the highest number of final homestead entries—37,568, covering 5,241,120.76 acres—was made in 1901, the entries for the year ending June 30, 1908, were 29,636, covering 4,242,710.59 acres, which number was exceeded only in the years 1901 and 1902. The people themselves, therefore, are showing concretely that the inducement to enter public land need not now be increased, since the desire to secure a homestead of 160 acres is still strong enough to increase rather than diminish the number of entries.

In other respects the public-land laws, as they exist to-day, do not, either in their substance or in the limited opportunities for strictly administering them, furnish the necessary protection to the people's interest in the public lands. Changes are necessary, not only because the present laws are not suited to existing conditions, but also partly because these laws, as originally drawn, contemplated conditions and needs which have been greatly modified by unforeseen political, social, and economic conditions, and by decisions of the Land Department and of the courts which were not foreseen by the lawmakers. This will be noted in connection with each law considered. The conditions are described in an appended paper by Mr. H. H. Schwartz, chief of special agents, General Land Office.

LAND CLASSIFICATION.

Because of the diversified condition of the public lands there is need to know, for reasonably small areas, whether the surface is chiefly valuable for agricultural purposes, for timber, or for grazing purposes. As to what is beneath the surface, we need to know whether the land is mineral or nonmineral. The mineral lands must be subdivided into various classes, according to the kind of mineral. With reference to the surface, the main classification must be into timber, grazing, and agricultural land. Having once admitted that the surface of all lands should, except in so far as it is actually needed for exploiting the minerals beneath it, be acquired by those who will best use it for the public welfare in lumbering, grazing, or agriculture, and that the minerals themselves should be exploited in reasonably large but limited areas by those who have the knowledge, skill, and capital, it follows irresistibly that no scheme of public-land laws can be thoroughly effective for the purposes for which they are enacted, unless they provide for or allow an authoritative classification of the lands. The power to classify should, as a matter of course, carry with it the power to reclassify when changing conditions or newly discovered evidence show that the lands involved should be differently classified.

The cost of classification will necessarily be considerable, but it will be possible, by prompt and skillful classification, to save the Government amounts many times greater than the cost, without requiring more than reasonable prices for any lands and none for those disposed of for home making. Scientific classification would ultimately fix with certainty, according to the productive value of the surface, a reasonable home-making area for each class of agricultural land, and thus solve that problem without mistake or friction.

A discussion of the question of classification by Hon. Fred Dennett, Commissioner of the General Land Office, is appended.

TIMBER AND STONE ACT.

The timber and stone act of June 3, 1878, was passed in order to give the home maker a timber lot to be used in conjunction with his homestead. This is evidenced by the debates in Congress at the time of the passage of the act; also by the provision that the applicant to purchase must declare "that he does not apply to purchase the same on speculation, but in good faith to appropriate it to his own exclusive use and benefit." As the timber of the country was cut off and destroyed by reckless lumbering and forest fires, the value of timber land increased with great rapidity. The farsighted lumber operators foresaw that the value of the fine timber would increase for some time in geometrical progression. They therefore followed a natural business instinct, and began to take advantage of the timber and stone act to acquire the best forests in the West. They employed cruisers, who went over and determined the value of the various legal subdivisions containing heavy stands of timber. They allowed the public to know that they would purchase certain timber land from any who might enter it under the timber and stone act. In some instances they imported shiploads and carloads of their employees and other persons, furnishing them with the necessary funds to buy. These persons entered valuable contiguous quarter sections, and transferred them wholesale to their principals. A specific instance is that in Modoc County, Cal., where more than 85 per cent of about 25,000 acres of timber land entered in one calendar year was transferred before May 1, as was shown by a search in the recorder's office of the county. Over 14,000 acres of this went to one man, and the bulk of the rest to three others.

It is clear that the timber and stone act does not fulfill the purpose for which it was passed, and that it should be repealed.

COMMUTATION CLAUSE OF THE HOMESTEAD ACT.

The Commission on the Public Lands, in its report and appendix of February 13, 1905, shows with great clearness that the commutation provisions of the homestead act open the door to immense possibilities for fraud. The illegal acquisition at $1.25 per acre of land worth ten or even a hundred times that sum easily follows the opportunity. Quarter sections covered with heavy timber are often worth from $10,000 to $20,000 or more; and it is well worth a man's time and expense to build a small shack and actually live on such land for fourteen months in order to acquire it. To do certain small acts of improvement during this time is a matter of small moment to the mala fide settler. The net gain, if the entryman sells the land for anywhere near its value at the end of the time, is often at the rate of several thousand dollars per year. Even so, there is strong reason to believe that most of those who acquire lands fradulently under the commutation clause do not profit to any great extent, but are paid only a small wage for giving their time and homestead right to others who wish to acquire the valuable land in defiance of law.

The commutation provisions of the homestead act should be absolutely repealed, and anybody wishing to obtain land from the United States, free of cost, should show the bona fides of his intent to make it his home by living there the full five years required by the homestead act.

An alternative recommendation would be that after three years bona fide and continuous residence at home on the land, an entryman may commute it if his improvements and cultivation are so ample that they show beyond a doubt that he is taking the land for farming and not for other purposes.

It is recommended strongly that no commutation should be allowed for land covered with valuable timber unless sufficient clearing and successful cultivation have been made to remove any doubt as to the intent of the entryman; also that grazing only should not be allowed as sufficient cultivation of land to warrant commutation.

The grounds for these recommendations are set forth by Mr. Schwartz, chief of special agents, General Land Office, in an appended paper.

DRY-FARMING LANDS.

The principle that land capable of agriculture should be given to the home maker only in such areas as will by farming maintain an average family in reasonable comfort is commended. In certain localities dry farming would be successful on land which does not contain water for drinking and other domestic use. In these cases the home can not be maintained on the land itself, and it would seem wise to allow it to be established at some place near enough to serve as the base of operations for improving and actually cultivating the land entered; but successful production of crops and a continuous home in the neighborhood should be required.

DESERT-LAND LAW.

The Public Lands Commission, in its reports of 1904 and 1905, showed that the practical working of the desert-land law is lamentable. The small force of special agents and inspectors at the command of the Land Department and the heavy burden of routine work devolving upon them in the way of hearings has made it impossible thus far to investigate by government agents whether the reclamation work and improvements claimed have actually been made. The fact that the land can be obtained in larger quantities than under any other agricultural law offers an inducement to fraud, and there are usually others interested, by reason of being like circumstanced, who are available for manufacturing proof on the record when the facts upon the ground are absurdly deficient.

The desert-land law might possibly be repealed in toto without harm to the best interests of the people in its public-land property. Such a repeal would not make it impossible for a man to get possession of land desert in character by living on and reclaiming it under the homestead law, but there are those who claim that the requirement of residence is incompatible with the desert character of the land, and that a home can not be established or maintained until after the land is reclaimed. In deference to the view that such land would remain unreclaimed if it were not for a law similar to the desert-land act, it is recommended (1) that entry be limited to 160 acres; (2) that residence to the exclusion of a home elsewhere must be established by the entryman within three years after the original entry; (3) that the entryman must prove that he has actually resided upon the land for two full years immediately preceding the date of final proof; (4) that final proof must be made not less than four nor more than seven years after the original entry; (5) that final proof must show that at least one-fourth of the land has been successfully cultivated to crops by irrigation for two successive seasons; (6) that no commutation be allowed; and (7) that there shall be no charge to entrymen except the fees required in homestead cases.

The object of these modifications is to accomplish the purpose of the present desert-land act, namely, an actual reclamation of land, and at the same time maintain the best features of the homestead law. The matter is discussed in an appended paper by Mr. W. B. Pugh, of the General Land Office.

GRAZING LAND.

There are more than 300,000,000 acres of public land, of which the surface can not at present be successfully farmed. This is an area more than ten times as large as Ohio. Nearly all this land can be used for grazing. Under existing law any person can at any time take any number of any kind of live stock upon any part of this public range. To obstruct or try to prevent him is a criminal offense. Under these circumstances nobody has either the power or inclination to prevent overgrazing. The result is that the range is overstocked, and the forage is rapidly deteriorating both in quantity and quality. As the grazing grows poorer, there is no tendency to diminish the overstocking. Each stockman wants his neighbor to do that. Meantime changed conditions of transportation and market make the raising of sheep more profitable than cattle growing, with the result that sheepmen have for years been crowding on the already overstocked range, and their sheep have hastened the destruction of the forage plants. Contentious strife, destruction of property, breach of the law, and even murder, have followed.

It is recomended that the surface of the remaining public domain be dedicated by law to grazing purposes with reasonable regulation, (1) to insure that the land may be entered at all times under the homestead laws for the bona fide purpose of home making, (2) to protect the rights of those who already have stock on the public domain, (3) to allow fencing for individual or community use, (4) to impose such conditions in the permits as shall prevent overstocking and gradually bring the range back to its full forage capacity, and (5) to make sure that the distribution and use of grazing rights shall be equitable and shall carry with it the indispensable element of business certainty concerning duration and conditions of the permit.

Discussion of the grazing lands appears in appended papers by Mr. A. F. Potter, of the Forest Service, and by Mr. A. D. Melvin, of the Bureau of Animal Industry.

RIGHTS ANALOGOUS TO SCRIP.

There are various "location, selection, and scrip" rights outstanding against the public domain. These are rarely used for the making of homes. Some of them have been in existence over half a century, and are yet unused. They originally were supposed to have a value of only $1.25 per acre, but the growth of the country and changed conditions make them worth now from $10 to $20 per acre. These rights are a source of never-ending difficulty and embarrassment in the administration of the public land. It is strongly recommended that Congress pass a law for their retirement which will fix a reasonable limit of time in which they may be located, or selections made as the case may be, after which the rights shall be redeemable in cash. An appended paper by Mr. S. W. Williams, of the General Land Office, gives details.

SEPARATION OF RIGHTS.

In 1906 the Interior Department discovered that vast areas of coal lands were being taken up with or without knowledge of their coal character under the various nonmineral laws. President Roosevelt, to prevent this improper and wasteful disposal of coal, withdrew over 68,000,000 acres, all or part of which in each township involved were known by the Geological Survey to contain coal. It is not lawful to take coal land under the homestead law. Therefore, as the law stands to-day, more than 50,000,000 acres, much of the surface of which is valuable for farm homes, is withheld from the homesteader, and unless the law is changed that fundamental principle of national efficiency, which demands that the agricultural lands be placed free of charge in the hands of agricultural home makers, can not be applied to this land, because the surface must eventually, by purchase of coal and surface together, under the coal-land laws, fall into the hands not of homesteaders, but of miners. On the other hand, President Roosevelt was so convinced that the agricultural land laws should not be used for the purpose of acquiring coal lands that he has, by withdrawal and classification, dedicated the above-mentioned vast area of coal entry, but, to protect the homesteader, has urged Congress to amend the public-land law so that a homesteader can get freely what he ought to have and the miner get only full opportunity to mine his coal without holding farming land away from agricultural home makers, either at prohibitive prices or as the foundation for tenant farming. The accompanying paper by Hon. Fred Dennett, Commissioner of the General Land Office, discusses the matter fully.

MINERAL LANDS.

There is no way to use both the surface and the resources beneath it to their best advantage in the long run for the largest number except by disposing of them separately. Our present knowledge of the needs of the country does not warrant recommendation that the precious metals be disposed of otherwise than by sale, either with or without the surface; but the following recommendations seem fully justified:

(1) That the area of lands containing precious metals entered by any one person or association should be definitely limited, and that entries made on reserved lands should give title to only so much of the surface as may be found reasonably necessary for exploitation of the minerals. This is in line with the fundamental principles of preventing monopoly and devoting the surface of the land to its highest use. The limit should not be so low, however, that it will interfere with the economical exploitation of the resources as viewed from the business standpoint.

(2) That all locations must be filed at the local land offices within six months of their initiation. This is absolutely demanded by the need for the Land Department to know when a claim is initiated against the public land.

(3) That a location be considered abandoned unless followed by final proof and cash entry within a reasonable limit of time. The reason for this is that right to mineral land should go only to bona fide miners, not to speculators, and that a locator should make good his claim or get out of the way reasonably soon.

The reasons for these recommendations are stated in an appended paper by Mr. E. C. Finney, of the General Land Office.

COAL LANDS.

With regard to coal lands, it is clear that the coal still owned by the people, when classified by the Geological Survey, should be disposed of under leases only. The present coal-land law makes it impossible for any one association of persons to obtain legally more than 320 acres. This is not sufficient for the conduct of an economical mining business. The area which may be leased should be increased materially. It is recommended briefly as follows: (1) That in this and in all changes of the law valid existing rights should be protected; (2) that, except for rights already initiated, no patents or final certificates issue for any public lands, except with a specific reservation of the coal; (3) that the patents also reserve specifically a reasonable provision that the miner may, with compensation to the surface owner, acquire such part of the surface as may be needed in producing the coal; (4) that provision be made for reasonable damages if mining operations injure any property of the owner of the surface; (5) that the Secretary of the Interior shall lease the public coal lands under such regulations as he may deem wise for the protection of the public interest, in such reasonably limited areas, with such charges, and for such reasonable periods as may be fixed and made certain in each lease; and (6) that, at the discretion of the Government, the lease may be renewed or the lessee compensated for his improvements after termination of the lease period by a method fixed in each lease.

Details appear in appended papers by Mr. T. J. Butler, of the General Land Office.

OIL, GAS, AND OTHER NONMETALLIC MINERAL LANDS.

Oil, gas, and other nonmetallic mineral lands can at this time be acquired under the placer mining law, which means that any person can get possession of as much land containing such minerals as he can discover and locate, even though it were millions of acres, and that he need not buy from the Government unless and until he desires. When this is compared with the restriction of coal land to 320 acres, the ill logic of both laws is evident. It is recommended that these minerals should be disposed of under practically the same conditions as recommended above for coal.

RIGHTS OF WAY.

No public-land laws fall so far short of being right and equitable as those which provide for rights of way. In many instances the most important of these laws fail to give that certainty to the grantees or permittees which is absolutely necessary for business security. In other instances they give rights so far-reaching that the equity of the people in the subject of the permits is forever lost. In other cases the exact nature of the grant is subject for grave dispute between permittees and the Government. The laws should be indubitably certain and just both to the people and to the permittees. It is recommended that all the right-of-way laws be codified and made just, reasonable, and certain. They should give to the permittee security against revocation, except for nonuse or misuse, and a sufficient period of enjoyment. The people, on the other hand, should have, among other reservations to reasonably safeguard their welfare, the certainty that at some reasonable time in the future the subject-matter of the permit will return to their control to be disposed of according to the demands of the public welfare at that time. The right-of-way laws should also provide a definite procedure for the revocation of any right of way because of willful and continued nonuse or misuse of the privilege.

TIMBER UNDER THE CONTROL OF THE UNITED STATES.

Outside of the meager quantities of poor timber remaining upon the unappropriated public domain, the timber still belonging to the United States is 70 per cent in the national forests and 30 per cent in national parks and Indian reservations. Most of the timber in the parks and Indian reservations is not only valuable to the people as a possible future timber supply, but is also of the highest importance, like that upon the national forests, to conserve the run-off of water. Government reserved timber land also conserves natural scenic beauties and wonders, furnishes a health and pleasure resort of value to the people, and stands as a last refuge for the preservation of certain wild animals, birds, and fish, which would otherwise be exterminated. It is recommended that the administration of all the timber lands of the United States be delegated to that governmental agency most fitted to care for it. At the present time the timber of national parks and Indian reservations is suffering badly from lack of broad and scientific management.

CONCLUSIONS CONCERNING THE PUBLIC LANDS.

1. The remaining public lands should be properly classified.
2. Modifications of the public-land laws should protect carefully all rights initiated prior to such changes.
3. The public-land laws should provide for every contingency which might arise in connection with the conservation and administration of the land and other resources belonging to the United States, and should intrust each class of stewardship to that governmental agency best fitted to handle it efficiently.
4. The surface chiefly valuable for agriculture, independent of the disposal of the resources beneath the surface, should be given only to actual homemakers in areas reasonably capable of supporting a family.
5. The surface more valuable for conserving water run-off, unusual natural scenic beauties or wonders, and timber, than for homemaking, should be held by the Government, independent of the disposal of the resources beneath the surface, for the use of all the people, and maintained effectively in a condition to insure its highest efficiency for all time; but such exploitation should not be allowed to impair in any way national parks or national monuments.
6. The right to exploit the mineral resources belonging to the nation and to use a sufficient part of the surface therefor, should be granted to those who actually intend to exploit them, in such limited areas, for such periods, and under such conditions as will, for each class of mineral, bring about seasonable and economical exploitation, but prevent such monopoly as might injure the interests of the people.
7. Rights of way should be allowed for definite and limited periods only, varying for each class of right of way, with reasonable conditions to protect the public interest in the subject-matter and use of the permit and with such certainty to the permittees against revocation during the permit period, for any cause except nonuse or misuse.
8. Pending the disposal of any public land by reservation for public use or by appropriation under the public-land laws, it should be protected by the Government from deterioration and administered so as to serve the best interests of all the people.

So much of the foregoing statement as pertains to the "use and abuse" of our lands was prepared chiefly by Mr. Henry Gannett, of the United States Geological Survey, geographer of the National Conservation Commission.

GEORGE W. WOODRUFF,
Secretary Section of Lands.

MINERAL RESOURCES.

SUMMARY.

The annual products of the mines of the United States now exceed $2,000,000,000 in value. They contribute 65 per cent of the freight traffic of the country. The industry employs over a million men at the mines, and twice that number in handling, transporting, and manufacturing the products.

The waste or losses in the mining, preparation, and use of the mineral products is estimated to exceed $1,500,000 per day.

The available and accessible commercial coal in the United States aggregates approximately 1,400,000,000,000 tons. At the present increasing rate of production this will be depleted and will approach exhaustion before the middle of the next century; and the additional 1,600,000,000,000 tons of inferior coal and lignite not now available economically will approach exhaustion before the end of the next century.

The known supplies of high-grade iron ores in the United States approximate 4,788,150,000 tons, which at the present increasing rate of consumption can not be expected to last beyond the middle of the present century. These are also estimated to be 75,116,070,000 tons of low-grade iron ores which may hereafter be available.

The known supplies of petroleum, natural gas, and high-grade phosphate rock can not be expected to supply the nation's needs through the present century.

The losses from fire in the United States during 1907 were approximately $450,000,000, of which some $400,000,000 was preventable waste.

During 1907 we produced 480,000,000 tons of coal, and the annual production has increased at the average rate of more than 7 per cent. We also produced 52,000,000 tons of iron ore, and the production since 1880 has increased at the average rate of 110 per cent during each of the three decades. In 1907 we produced nearly 870,000,000 pounds of copper; more than 17,000,000 pounds of aluminum; 365,000 tons of lead; 223,000 tons of zinc; 166,000,000 barrels of petroleum; 52,000,000 barrels of cement; 30,000,000 barrels of salt; more than 2,265,000 tons of phosphate rock; and we also extracted clay products to the value of $159,000,000; natural gas, $53,000,000; stone, $71,000,000; gold, $90,400,000; and silver, $37,000,000.

The total value of our metallic products during 1907 was $900,000,000; of mineral fuels, $788,000,000; and of nonmetallic mineral products, other than fuels, more than $378,000,000.

During 1907 our production was 40 per cent of the world's production of coal; 45 per cent of the world's production of iron ore;

22 per cent of its gold; 30 per cent of its silver; 33 per cent of its lead; 27.5 per cent of its zinc; 54.6 per cent of its copper; 52 per cent of its phosphate rock; and 63 per cent of its petroleum.

During the year we imported mineral products to the value of $255,000,000 and exported mineral products to the value of $340,000,000.

BASIS OF ESTIMATES.

Our mineral wealth deserves special consideration and treatment, for the reason that it can not be increased or reproduced. The water for power and other purposes comes and goes continuously up to its limit; the grain crop of one year is succeeded by that of another; within a century one forest may replace another; by still slower process and at great cost the soils which are now being eroded may be replaced from the subsoil or the decay of rocks below; but the deposits of coal which have accumulated during the geologic ages of the past were finished long before man came into existence, and there is but the one supply. As this coal is used it is completely destroyed. No new supply will come when the one now existing is exhausted. The destruction of the metals is slow, but the ore supplies are far more limited than the coal. Of these also there is but one supply; and the metals themselves are slowly but certainly wasted by wear and by various destructive agencies.

The need for an inventory of the mineral resources of the nation grows out of the fact that the production and consumption of these resources are increasing at a rapid rate, and that the mineral supplies for future use are limited.

We should therefore know the quantity of each of these resources available for future use; the increasing rate at which they are being produced or consumed; and the probabilities as to the continuance of this increasing rate. From such data we may form at least an approximate estimate as to the duration of the supplies; and through adequate investigations we may determine the possibilities of increasing the duration of these supplies by developing more efficient methods of production and use.

The incompleteness of the available data renders the making of an inventory of mineral wealth more difficult than that of forests and water resources, and illustrates the need of further investigation. However, the coal fields have been mapped with such accuracy that future discoveries of coal outside of the limits indicated for existing fields are not likely to exceed 1 per cent of the total known supply; and future investigations are likely to diminish rather than increase the estimates of the quantity available within these limits.

Our knowledge of the quantity and distribution of other minerals is less definite, but enough is known to prove that the deposits are limited in extent, and that at the present increasing rates of consumption the supplies of many important minerals will be largely depleted or exhausted before the nation has added another century to its history.

The data for this inventory have been prepared by experts of the United States Geological Survey from records of their investigations and other sources. In the papers by these experts accompanying the commission's report the data are given in detail.

It is not claimed for the statements presented in this inventory of the mineral wealth of the country that the data in all cases are of quantitative exactness or that all the data are of the same degree of accuracy in detail; but all available data have been considered, and only such as are deemed reliable have been used.

Even should future development prove that these estimates are 10 or 20 per cent in error, the need for a wise conservation of resources would stand out none the less prominently and positively. Thus the data for the estimates of coal have been published and distributed among geologists and mining engineers for six months, and the only changes suggested have indicated that the estimates are too high, and that the figures for the duration of the supplies should be reduced rather than increased.

FUEL RESOURCES.

Of all our minerals, the fuels which supply heat, light, and power for domestic and industrial purposes are the most fundamentally essential to the nation. The use of fuels involves their immediate and complete destruction; and increase in the use of other materials also increases the consumption of fuels for both metallurgical and manufacturing purposes, for as the nation has now passed its early development stage, manufacturing, with consequent use of fuels, will increase much more rapidly than will population. A more thorough inventory of the fuels (coal, oil, gas, and peat) is therefore of prime importance.

COAL AND ITS DISTRIBUTION.

The following estimates concerning the original supply, production, and ultimate exhaustion of coal in the United States were prepared by Messrs. M. R. Campbell and E. W. Parker, of the United States Geological Survey, and are based largely on their own investigations, supplemented by data obtained from state geological surveys and private mining companies.

The areas occupied by the anthracite, bituminous, and lignite coal fields aggregate 496,776 square miles, or about 17 per cent of the total area of the country. It is estimated that these coal fields contain a total of 3,000,000,000,000 tons of coal, of which about one-third is regarded as accessible only with difficulty, and not available for mining at the present time. Of the total amount, 1,400,000,000,000 tons of high-grade coal are considered both easily accessible and available for mining under existing conditions.

The geographic distribution of the total coal supply, including that easily accessible and available and 500,000,000,000 tons not now available, is as follows: East of Mississippi River, 800,000,000,000 tons, distributed over an area of 138,022 square miles; west of the Mississippi and east of the hundredth meridian, 160,000,000,000 tons, distributed over an area of 63,044 square miles; in the Rocky Mountain region, including the Great Plains area of Wyoming and the two Dakotas, 930,000,000,000 tons (largely lignites), distributed over an area of 124,700 square miles; and in the Pacific coast States, 10,000,000,000 tons, distributed over an area of 1,830 square miles.

The easily accessible and available anthracite and bituminous coals occupy a total area of 250,531 square miles, and aggregate about 1,160,000,000,000 tons; the lignites, occurring mainly in the Dakotas, Montana, Utah, Colorado, New Mexico, Texas, Louisiana, Mississippi, and Alabama, occupy a total area of 148,609 square miles, and aggregate 385,000,000,000 tons; and the accessible subbituminous coals, ranging in quality between the bituminous and lignite, occupy an area of 97,636 square miles in Montana, Wyoming, and the Rocky Mountain region, and aggregate 355,000,000,000 tons.

The several varieties of bituminous and subbituminous coals and lignites differ to a considerable extent in their composition and heating value, but after giving due consideration both to the quantity and quality of the different coals, it is calculated that the geographical center of coal distribution in the United States is at a point in southeastern Nebraska.

PRODUCTION AND DURATION OF SUPPLY.

From the beginning of coal mining in this country (1814) to the close of 1907 there were mined nearly 7,000,000,000 (6,865,000,000) tons. Adding to this the one-half additional, representing the waste in mining, gives a total of more than 10,000,000,000 tons taken from supplies originally available.

The rate of production has increased rapidly. The average increase from 1846 to the close of 1907 was 7.36 per cent per annum, practically doubling the production every ten years. There has, however, been a decreasing rate of increase in production when considered on a basis of twenty-year averages, and Mr. Henry Gannett, of the United States Geological Survey, on this basis estimates the easily accessible and available coal supplies, aggregating 1,400,000,000,000 tons, would be exhausted by about the year 2027, and that the entire coal supply would be exhausted about the year 2050.

As a practical matter it should be understood that coal production will not increase to a certain point and then cease, but that long before the time of exhaustion of supply has been approached there will come a gradual decline in annual production of coal owing to its increasing scarcity and cost. Already the price of anthracite and some other coals is advancing because of exhaustion of thicker beds and increased cost of working.

The adoption of more efficient methods in connection with the mining and utilization of coal, and the increasing use of water power and other substitutes for fuel in power development will diminish the present increasing rate of consumption, and thereby extend the life of our coal supplies beyond the dates mentioned. On the other hand, it is to be expected that manufacturing will continue to grow more rapidly than population, and this will increase the rate of coal consumption for power purposes even more rapidly than for heating.

The factors in the above estimates are sufficiently reliable to make it clear that without a serious lessening of the present rate of coal consumption, either through more efficient use of this fuel or through the extensive development of substitutes for it, long before the middle of the next century is reached the nation's supplies of available coal will be so largely depleted as to bring serious hardship and a curtailment of industry.

In the earlier days of anthracite coal mining, and in fact until within the last ten years, 40 per cent of the contents of the coal fields was considered a maximum recovery, but conditions have so improved, both in the adoption of better mining methods and in the utilization of what were formerly considered waste sizes, that 60 per cent may now be considered a fair estimate of the coal recovered for commercial use.

It is probable that up to the present time the total loss in the mining and use of bituminous coal has been over 50 per cent of the production. During the last few years, however, the percentage of loss in mining the higher grades of bituminous coal has been largely reduced. This 50 per cent waste includes the coal left in the mine workings for the support of the roof, the coal of lower grades left as unprofitable at current prices, that which is unworkable because of such structural difficulties as faults or dikes and pinchings, and also that rendered unworkable by breaking up due to prior removal of the underlying beds.

The estimated loss in the transportation of anthracite coal is about 2 per cent, and that for bituminous coal is doubtless much larger. On the basis of the 1907 production, this means an annual loss from this source alone of 1,700,000 tons of anthracite coal.

No accurate estimate can be made as to the total unnecessary losses in connection with the use of coal for different purposes, but lines of urgently needed investigation are indicated by the facts that the vast majority of the power plants of the country convert less than 10 per cent of the heat units in the coal into actual work, and that lighting plants convert less than 1 per cent of the heat value of the coal into electric light. The large amounts of gases from blast furnaces are being used to a small but increasing extent in the development of gas-engine power. In the coking industry gases and other by-products to the value of $55,000,000 went to waste in 1907.

EXTENDING THE DURATION OF THE SUPPLY.

The first step in extending our fuel supply should be to lessen the waste in mining, handling, and transportation of coal. There are equally great possible savings in the use of coal, not only in preventing waste now recognized as such, but also in discovering means of avoiding the losses involved in the transformation of heat into mechanical energy, and this into electric energy and light.

Water power will doubtless prove a valuable substitute for coal in the development of power and light in many parts of the country, and the use of the heat of the sun and of alcohol and other organic fuels as substitutes for coal is worthy of serious consideration and investigation.

PEAT.

In European countries where fuel is expensive 10,000,000 tons of peat are used annually for fuel purposes. A preliminary and incomplete examination of the peat beds of the country has developed the fact that they extend over an area of more than 11,000 square miles, the larger part of which is distributed through the New England States, New York, Minnesota, Wisconsin, New Jersey, Virginia, the

Carolinas, and Florida—States which contain little or no coal. Extensive deposits are also found in a few coal-producing States—Iowa, Illinois, Indiana, Ohio, North Dakota, and South Dakota.

This area indicates a possible production of 13,000,000,000 tons of air-dried peat fuel. At $3 per ton in the air-dried form (which would be a reasonable price for fuel in the States having but little coal) this peat would have a fuel value of $39,000,000,000. If all of it were used in by-product gas producers, 640,000,000 tons of ammonium sulphate could be manufactured as a by-product, and at current prices this would have an aggregate value of more than $36,000,000,000.

Recent investigations have shown that much American peat, when dried, will be admirably adapted for use as a source of producer gas for charcoal, for certain grades of coke, for the production of various by-products, for illuminating gas, as a filler for fertilizers, in the manufacture of paper, and for packing material.

PETROLEUM.

The proved oil territory in the United States has fairly exact limitations, but the available information concerning the lateral exhaustion of the pools in this territory and the possible discovery of additional pools is too incomplete to permit of its use as a basis of prediction. Special investigations into the supplies and production of petroleum have been conducted by Dr. David T. Day, of the United States Geological Survey, and these investigations, together with the facts given in the volumes on Mineral Resources of the United States and in the reports of the several state geological surveys, have yielded fairly accurate information concerning the known oil supplies of the country.

The six known petroleum fields aggregate 8,450 square miles, distributed as follows: The Appalachian field, in the States of New York, Pennsylvania, Ohio, West Virginia, Kentucky, and Tennessee; the Lima-Indiana field, in Ohio and Indiana; the Illinois field, in eastern Illinois; the Mid-Continent field, in Kansas and Oklahoma; the Gulf field, in Texas and Louisiana; and the California field. Of these the Illinois, Gulf, and California fields lead in production. The development of these fields has shifted the center of petroleum production rapidly westward to Oklahoma. The yield of oil is from 1,000 to 10,000 barrels per acre, and the total available supply in these fields is estimated at 10,000,000,000 to 24,000,000,000 barrels; perhaps 15,000,000,000 barrels may be taken as a fair average estimate of the available supply. There is, of course, the possibility and even the probability of the discovery of other oil fields as explorations are extended, but these figures must be considered as representing our actual knowledge of the oil resources of the United States.

In 1907 the petroleum production amounted to 166,000,000 barrels. The total amount produced during the last half century is more than 1,800,000,000 barrels. A careful study of the increase in rate of production and consumption during that time indicates that if this increase continues the supply of petroleum will be exhausted before the middle of the present century. However, the present production of petroleum is greater than the legitimate needs of the industry, and should be curtailed. The rapid decline in production of the fields in New York, Pennsylvania, West Virginia, Ohio, Indiana, and Kansas indicates that within a few years the petroleum supply must come in still larger proportion from the more western fields.

One of the essential uses of petroleum is for lubricating purposes. At present fully half a pint of lubricating oil is used for every ton of coal converted into power, and in many branches of industry the proportion of petroleum used is more than twice that amount. Another important use is lighting, and this use also is practically essential, as a greater waste of coal or other fuel is involved in all other forms of lighting.

Such waste as characterizes the natural-gas and coal industries has been remarkably absent in the handling of petroleum in this country. The chief waste which needs mention here is its extensive misuse for purposes that could be easily met through the use of other materials.

During last year 35,000,000 barrels of crude petroleum were burned as fuel in locomotives and steamships and for general power development.

The large exportation of petroleum (30,000,000 barrels in 1907) is still more inimical to the future welfare of the industry. Decidedly beneficial results in extending the life of the supply would come through discontinuance of exportation and decrease of use for fuel.

NATURAL GAS.

Recent investigations of natural gas by the United States Geological Survey, through Dr. David T. Day, show that the known productive territory covers an aggregate area of 10,000 square miles, distributed through 22 States—Alabama, California, Colorado, Illinois, Indiana, Kansas, Kentucky, Louisiana, Michigan, Missouri, Montana, New York, Ohio, Oklahoma, Oregon, Pennsylvania, South Dakota, Texas, Utah, Washington, West Virginia, and Wyoming. Some of the gas fields were at one time abandoned as exhausted, but have subsequently been successfully operated for a time, although under greatly reduced pressures. The life of all the older gas fields, for example, those in portions of Pennsylvania, West Virginia, Ohio, and Indiana, is being exhausted by pumping, and the quantities of gas thus obtained have been unexpectedly large.

Records of the quantity of natural gas have been kept for the last two years only; the value of the annual output is known for the last twenty years or more. The production in 1907 was more than 404,000,000 cubic feet, with a value of more than $52,800,000. The total value recorded by the United States Geological Survey for the twenty years from 1888 to 1907 was $493,649,273.

It is impossible to estimate with even approximate accuracy the total quantity of gas still available for future use in the United States. However, in view of the fact that the known productive areas are limited and the quantity of gas produced in a number of the older fields is diminishing, it is safe to predict that within twenty-five years the known fields will be exhausted.

The waste of natural gas has been one of the chief sins in several States. Drillers for oil have incidentally tapped underground stores of natural gas, and have allowed it to escape until the oil could be produced. Dr. I. C. White, state geologist of West Virginia, estimates that the waste in this manner is now equivalent to a billion cubic feet per day, and has continued for a number of years. In the

Caddo field of Louisiana the daily loss of gas at the present time is estimated as 70,000,000 cubic feet, enough to light ten cities of the size of Washington, and equivalent to a waste of 10,000 barrels of petroleum per day.

This waste indicates most clearly the need of State laws to prohibit the squandering of our natural resources. Such laws applying to natural gas have already been enacted in Indiana, Pennsylvania, and Ohio, and have given gratifying results; and the country will be greatly benefited when other States follow this good example.

The prompt development of new fields of industrial enterprise to utilize the gas or pipe it to existing centers of industry, and penalizing drillers who permit the gas to waste in the air, are urgently required for the conservation of this peculiarly valuable resource.

IRON ORES.

DATA AND CLASSIFICATION.

The iron ores of the United States have been classified by Dr. C. W. Hayes, chief geologist of the United States Geological Survey, with the collaboration of other geologists and mining engineers, on the bases of chemical composition, geologic relations, and geographic distribution. All these classifications have a direct bearing on the commercial value and utilization of the ores. The value of the estimates of tonnage varies widely with different kinds of deposits; about one-eighth of the deposits may be calculated within 10 per cent, nearly three-fourths within 15 to 20 per cent, and the remainder much less closely.

In estimating the tonnage, the ores are divided into (*a*) those available under present conditions and (*b*) those not now available, but which will be used eventually, the division resting on present and prospective costs of delivery to the furnace and of reducing the ore. Among the most important factors of cost are accessibility to transportation, concentration of the deposits permitting large-scale operations, depth below the surface, and composition of the ore, including both the iron content and the character of the impurities. All limy ores carrying over 20 per cent of iron and all siliceous ores carrying over 35 per cent are considered eventually workable, also all material carrying over 4 per cent of wash ore, and all such ores known to occur in the United States are included in the estimates.

The following ore deposits are sufficiently known to indicate the basis and quality of tonnage estimates: (1) Lake Superior ores; (2) Adirondack ores; (3) Clinton ores; (4) Appalachian metamorphic ores; (5) Appalachian brown ores; (6) Appalachian carbonate ores; (7) west Tennessee brown ores; (8) eastern Texas brown ores; (9) Ozark ores; (10) Rocky Mountain metamorphic ores; (11) igneous contact ores.

ESTIMATED SUPPLIES.

The estimates of ore supplies are summarized by districts on purely commercial considerations.

The ores now considered available are estimated to amount to 4,784,930,000 tons, distributed as follows: In the Northeastern States, 298,000,000; in the Southeastern States, 535,220,000; in the Lake

Superior district, 3,510,000,000; in the Mississippi Valley, 315,000,000; in the Rocky Mountain region, 57,760,000; and on the Pacific slope, 68,950,000 tons.

Of low-grade ores not available under existing economic conditions, but which the country may be forced to use in the future, there are estimated to be 74,881,070,000 tons, distributed as follows: In the Northeastern States, 1,095,000,000; in the Southeastern States, 1,041,500,000; in the Lake Superior district, 72,030,000,000; in the Mississippi Valley, 570,000,000; in the Rocky Mountain region, 120,665,000; and on the Pacific slope, 23,905,000 tons.

ORES AVAILABLE FROM OTHER COUNTRIES.

In addition to the ores tabulated, certain foreign deposits which are dependent on the United States market must be taken into account. The most important of these are in Canada and Cuba. Although the amount of iron in these deposits can not be stated with any definiteness, the subjoined table affords some idea of their magnitude. Probably about 5 per cent of the Canadian and from 25 to 40 per cent of the Cuban ores may be available under existing conditions.

Estimated foreign ores tributary to the United States.

	Tons.
Canada and Newfoundland	73,000,000
Cuba	1,505,000,000
Total	1,578,000,000

During the four years 1904 to 1907, inclusive, iron ores were imported into the United States from Cuba, Spain, French Africa, Greece, Newfoundland, Labrador, the United Kingdom, Germany, Holland, Canada, Belgium, France, Norway, British India, and to a less extent from several other countries. The value of the importations steadily increased from $1,101,384 in 1904 to $2,062,161 in 1905, $2,967,434 in 1906, and $3,937,483 in 1907. The tonnage increased from something like 500,000 to about 1,375,000.

PRODUCTION AND DURATION OF SUPPLIES.

Our production of iron ores by decades and the percentage of increase since 1870 (the production of 1908 and 1909 being estimated) were as follows:

Decade.	Production.	Percentage of increase.	Decade.	Production.	Percentage of increase.
1870-1879	49,022,990		1890-1899	183,667,896	80.10
1880-1889	101,969,116	108.00	1900-1909	445,373,480	142.40

The rates of increase are not such as to permit the construction of a curve by which the future production can be predicted. If the average increase of 110 per cent should continue, it would require the production during the next three decades of over 6,000,000,000 (6,329,000,000) tons. The supply of ore now available in the United

States is estimated at 4,784,930,000 tons. It is evident, therefore, that before 1940 either (1) the production will have reached a maximum and begun to decline, or (2) large use must be made of low-grade ores not now classed as available—else the importation of foreign ores must be greatly increased. It should be remembered that in the future use of low-grade ores the conditions will be rendered still further unfavorable through the necessary use of low-grade coals. In view of the many unknown features entering into the problem, the tendency and importance of which are not determinable, any more specific prediction as to the date of the ultimate exhaustion of the iron-ore supplies would be unwarranted.

WASTE AND EXTENSION OF ORE SUPPLIES.

Waste in the handling of iron ores in the Lake Superior district is being reduced to a small amount. The mining companies are displaying a commendable spirit not only in preventing waste of the high-grade ores, but in storing for future use the low-grade ores which it may be necessary to bring to the surface in mining operations, although not suitable for use under existing economic conditions. In other districts, especially those containing the Clinton ores, a considerable quantity of good material is at present left in the mines for the support of the roof. The waste in manufacturing is also guarded against with considerable care.

The principal factors in extending the duration of the supplies of high-grade ore will come through the utilization of the low-grade ore and through the lessening of the demand for iron and steel by developing substitutes for those materials in construction and other work.

GOLD, SILVER, COPPER, LEAD, AND ZINC.

Data concerning the ore supplies of these major metals have been prepared by Mr. Waldemar Lindgren, of the United States Geological Survey, whose report, largely based on the investigations of the Survey geologists, is appended.

THE ORE SUPPLIES.

The data are entirely inadequate for estimating the existing supplies of these metals, for the reason that they, or the ores from which they are produced, as a rule occupy comparatively small spaces, irregular and uncertain in occurrence, which can not be mapped and described with accuracy in advance of mining operations.

The areas in which these metals are known to occur, or where they may be reasonably expected to be found, are widely separated, and comprise in the aggregate less than one-third of the total area of the United States; and from this third may be excluded large areas in which the discovery of deposits is extremely unlikely.

The more important known available gold supplies are in Alaska, California, Colorado, and Nevada, all the other States contributing about one-fifth of the present total annual output. Silver is known to be mainly in Colorado, Montana, Utah, Nevada, and Idaho; lead in Missouri, Idaho, Utah, and Colorado; zinc in Missouri, New Jersey, Colorado, Wisconsin, and Kansas; and copper in Arizona, Montana, Michigan, Utah, Nevada, California, and Tennessee.

As compared to the certain future needs of the nation, the proved supplies of these metals are not great, but the discovery of large additional workable deposits is probable as the prospecting of the country is extended. Large deposits of low-grade ores are known to exist, which, although not now available for treatment, will become available as prices advance or as new processes permit handling and treatment at less cost.

PRODUCTION AND DURATION OF SUPPLIES.

A gold production of $60,000,000 was recorded in 1852 and 1854. From that time it decreased gradually to $30,000,000 in 1883, then rose to $33,000,000 in 1892. Since that time the increase has been rapid, and record figures of over $94,000,000 were reached in 1906. In 1907 the production fell to $90,400,000.

Important production of silver began about 1860 and rapidly increased, amounting to 63,500,000 ounces in 1892. Since then the output has remained practically constant, averaging about 55,000,000 ounces yearly.

Copper production has grown at a very rapid and almost constant rate, reaching its maximum in 1906, when the output was almost 918,000,000 pounds. In 1907 it declined to very nearly 869,000,000 pounds.

From 1885 to 1895 the lead production grew at a moderate rate from 129,000 to 170,000 tons. Since 1895 the increase has been much more rapid, and in 1907 the production was 365,166 tons.

Zinc production, which was of little importance in 1880, began to increase decidedly in 1896. In that year the spelter output was 81,000 tons, and in 1907 it increased to 223,745 tons. Including that manufactured into paint, the total production in 1907 was 280,676 tons.

As to the duration of the supplies, data are not available for specific estimates. With a continuation of the present increasing rate of production, the known ores workable under present conditions will be exhausted before the middle of the present century; yet no such prediction can be made without qualification. Full knowledge of our metal resources can be gained only by exploration, and exploration does not materially anticipate unusual demand. Ten years ago a review of our metal supplies would have revealed a greater shortage than now exists, and it is quite possible that in the case of some metals our visible stock may be greater some ten years hence than at present.

Improvements in processes are steadily reducing the cost of reduction, and this will bring many ore bodies of lower grades now considered unprofitable into the list of available supplies.

PHOSPHATE ROCK.

Mr. F. B. Van Horn, of the United States Geological Survey, has brought together all available information concerning the supplies of phosphate rock in the United States. These are distributed along the western coast of Florida, along the coast of South Carolina, in central Tennessee, and in an area recently discovered in southeastern Idaho, northwestern Wyoming, and northeastern Utah. The data are not sufficiently complete to make a trustworthy estimate of the total existing supply.

The best estimate of high-grade phosphate rock that can be made at the present time is as follows:

	Tons.
South Carolina	3,000,000
Florida	15,000,000
Tennessee	103,500,000
Western States (Idaho, Wyoming, and Utah)	100,000,000
Total	221,500,000

In addition there are large supplies of low-grade phosphate rock, carrying from 25 to 50 per cent of calcium phosphate, for which there is now no demand, but which may find a market after the high-grade rock, containing from 60 to 80 per cent of calcium phosphate, has been consumed. Doubtless the advance in price which will precede exhaustion will hasten the development of methods rendering the use of the low-grade rock possible. No quantitative estimate of low-grade phosphate rock can be made at present.

During 1907 the production of phosphate rock was 2,265,343 tons. The total amount mined from the beginning, in 1867, to the end of 1907 was about 29,200,000 tons. The rate of increase in production in the last twenty years has averaged 117 per cent for each decade. Should this rate of increase continue the available supply of high-grade rock will be exhausted in twenty-five years.

Increase in population and the development of intensive farming will eventually extend the demand for phosphates and other fertilizing materials already existing in the Southern States. A partial contribution toward meeting this future demand will come from a more complete and efficient use on the farm of animal excrement, including that which may be procured from sewage and other sources; but to meet any large demand for phosphate materials, recourse must be had to the mineral supplies.

It is probable that additional deposits of high-grade phosphate rock may be discovered, and the duration of the known phosphate product may be extended by more efficient methods of mining and treatment. In the phosphate industry the plan now in practice to some extent in iron mining, of laying aside for the future all material too low in grade for economical use at present, should be adopted.

Another means of extending the supply lies in discontinuing exports of this material. During 1907 the United States exported 1,018,212 tons of high-grade rock, or about 45 per cent of the entire output. The total amount of high-grade material exported during the last nine years was 7,504,519 tons.

MISCELLANEOUS MINERAL RESOURCES.

Many branches of our mineral industry are based on additional mineral substances, which occur in greater or less abundance. Of these the supplies of abrasive materials, as quartz, feldspar, garnet, grindstone, infusorial earth, millstone, oilstone, and such other minerals as mineral waters, mineral paints, low-grade graphite, talc, gypsum, and salt, appear to be sufficient to meet the needs of the nation's future as well as the present demands.

The supplies of sulphur, asphalt, magnesite, borax, asbestos, and fibrous talc, like those of coal and iron ores, are clearly soon exhaustible, though if wisely used they may be reasonably expected to extend beyond the limits of the present century. Our supplies of manganese ores, bauxite, quicksilver, antimony, high-grade graphite, corundum, and mica, like those of petroleum, natural gas, copper, gold, silver, lead, zinc, and phosphate rock, will be largely depleted or exhausted well within the present century unless known deposits are largely augmented by new discoveries. To this list may be added certain minerals of which only small quantities have yet been found in this country, such as nickel, cobalt, chromium, tin, platinum, antimony, bismuth, cadmium, tungsten, uranium, vanadium, molybdenum, and tantalum.

STRUCTURAL MATERIALS.

Data concerning the supplies and uses of structural materials and their waste through fire losses have been collected and prepared for the commission by Mr. H. M. Wilson, of the United States Geological Survey.

SUPPLIES AND USE.

The supplies of many of the materials used in building and engineering construction, such as stone, sand, gravel, clays, cement, lime, and salts, are practically inexhaustible, and for that reason need not be extensively discussed.

The use of these materials has been restricted heretofore by the wide difference in price between forest products and mineral products; but owing to improved methods the cost of the latter has been diminished, while that of wood products has advanced. Within the last decade the value of cement manufactures increased from $9,900,000 to $55,900,000, or nearly sixfold; and the value of clay products from $74,500,000 to $159,000,000, or more than double. In the same period the value of building stone increased from $28,600,000 to $71,100,000, or nearly threefold. A still larger relative increase in the use of these more durable building materials may be looked for, since the Government is determining the strength, durability, and fire-resistant properties of these materials, and is disseminating information as to the comparative cheapness of the more permanent work.

Through lack of exact knowledge as to the strength of these materials, present systems of building construction are expensive. Engineers and architects adopt working stresses for concrete and for metal construction ranging from one-fourth to as high as one-eighth the supposed working strength of the material, and this means that from three to six times the necessary amount of material is used.

WASTE OF MATERIAL.

The waste of minerals used in building and engineering construction comprises (1) that due to improper and wasteful methods of mining and preparing for market; (2) that due to the use of excessive quantities of material because of ignorance concerning strength and durability; and (3) that due to destruction by fire.

In addition to the waste of raw mineral products due to improper methods of mining and shipping, there is a large waste of material due to careless and inefficient methods of manufacture. Not until better knowledge is gained as to the appropriate structural material for each particular use—steel, iron, cement, or clay products—will it be possible to materially lessen this waste.

FIRE LOSSES.

The greatest source of waste of structural materials and of money values is fire. It is one which, from the example set in European countries, can be most rapidly reduced by the substitution of fire-resisting materials for the inflammable construction now prevalent.

The cost to the country of fire, including only property destroyed, was $217,500,000 in 1907. The cost of preventive measures, maintenance of fire departments, protective agencies, and additional cost of water supplies raised the total to over $450,000,000.

A notable fact in the analysis of fire losses is that 27 per cent were due to exposure—that is, the fire extending beyond the building in which it originated. The extension of fires results from the use of inflammable material in construction. It is even more notable that only $68,000,000 of the loss was on brick, concrete, stone, and other slow-burning construction, while over double that amount, or about $148,000,000, was on frame buildings. In the last thirty-three years the total fire waste amounted in value of property destroyed to over $4,500,000,000.

It is a reasonable estimate that one-fifth of the city water supply and distribution charges, three-fourths of the fire department charges, and over four-fifths of the fire losses, or a total of nearly $400,000,000 per year, may be considered a preventable tax on the nation.

CONSUMPTION AND WASTE.

The recent rapid increase in the production and consumption of mineral materials forms one of the important and striking general facts brought out in the work of the commission, and this fact is of vital importance in any consideration of the duration of these resources.

This consumption of mineral products has increased more rapidly than population. Thus, in 1880 we used 1.5 tons of coal per capita; in 1890, 2.5 tons; in 1900, 3.5 tons; and in 1907, 5.6 tons. Of pig iron we used in 1880, 200 pounds per capita; in 1890, 320 pounds; in 1900, 391 pounds; and in 1907, 686 pounds. Of copper we used in 1890, 3 pounds per capita; in 1900, 4.6 pounds; and in 1907, 6.4 pounds. Of cement we used in 1890, 70 pounds per capita; in 1900, 92 pounds; and in 1907, 228 pounds.

The striking features in the economic history of the nation during the past century were the development of agricultural and mining industries and the beginning of manufacturing and transportation. The striking feature in the economic development of the nation during the present century will be the rapid extension of manufacturing and transportation industries. This will both require and explain the continuance of a rapid increase in the rate of mineral production and consumption. Nothing can check this development save the premature depletion of the resources which are essential to its progress. The prevention of such depletion is worthy of the best effort of the nation itself.

While the data are not available for an accurate quantitative estimate of the losses connected with the mining, treatment, and use of our mineral resources, the facts in hand indicate that they exceed one-fourth of the total value of our present mineral production, or $500,000,000 yearly.

LOSS OF LIFE IN MINING INDUSTRIES.

Even more serious than the question of waste of materials is the excessive loss of life in our mining and metallurgical operations. During the past year in our coal mines nearly 3,000 men were killed and more than 7,000 were injured. During the past ten years nearly 20,000 men have been killed and probably 50,000 injured.

The number killed and injured in connection with metal mining and quarrying and in the metallurgical industries during the past year is not known, but the number will doubtless add materially to the sad record in the coal mines. The seriousness of this record is increased by the fact that the number of killed and injured for each thousand men employed in the coal mines was greater in 1900 than in 1895, greater in 1905 than in 1900, and greater in 1907 than during any earlier year of our history. This is the natural outcome of the deepening of mines and the employment of an increased percentage of untrained foreigners, rendered necessary in our mining operations by existing economic conditions. It is to be hoped that the record of 1907 represents the end of the increasing progression of killed and injured, and that henceforth loss of life will steadily and rapidly diminish through the cooperation of miners, operators, state and federal governments, and the general public.

A RATIONAL BASIS FOR THE CONSERVATION OF MINERAL RESOURCES.

In considering the conservation of resources it should be held in mind that:

(1) The present generation has the power and the right to use efficiently so much of these resources as it needs.

(2) The nation's needs will not be curtailed; these needs will increase with the extent and diversity of its industries, and more rapidly than its population.

(3) The men of this generation will not mine, extract, or use these resources in such manner as to entail continuous financial loss to themselves in order that something be left for the future. There will be no mineral industry without profits.

One of the essential steps is to adopt fundamental principles which give conservation as applied to mineral resources a rational basis. Some of the more important of these principles are as follows:

(1) The resources which have required ages for their accumulation, to the intrinsic value or quantity of which human agency has not contributed, which when once exhausted are not reproduced, and for which there are no known substitutes, must serve as a basis for the future no less than for the present welfare of the nation. In the highest sense, therefore, they should be regarded as property held in trust for the use of the race rather than for a single generation, and for the use of the nation rather than for the benefit of the few individuals who may hold them by right of discovery or by purchase.

(2) Measured in terms of the needs of a great and rapidly growing country, the mineral resources are limited in quantity.

(3) Measured in terms of the life of the nation, at the present increasing rate of consumption and waste we will, while the country is yet in its infancy, exhaust the resources necessary as the essential basis for the welfare of all succeeding generations. To shirk this responsibility on the claim that succeeding generations will probably discover other now unknown resources for their use is unjust and irrational.

(4) The right of the present generation to use efficiently of these resources what it actually needs carries with it a sacred obligation not to waste this precious heritage.

(5) The right to profit in the mining and utilization of our mineral resources does not carry with it the right to destroy the birthright of generations yet unborn, in order that we of to-day may obtain more easily and more cheaply the products we need for present use.

(6) It is therefore reasonable to expect that the users of mineral products will pay for them such higher prices as will make profitable their mining and preparation without serious waste.

(7) It is also reasonable to expect that the resulting increase in the first cost of the crude material will insure their more efficient use, and that this in turn will both help to keep down the ultimate cost of finished products and to conserve the resources.

(8) The very abundance and cheapness of our resources have developed an American habit of waste which is the greatest menace to our future welfare. This waste of the past and present entails on us a still greater obligation to strive for the highest possible efficiency in the future mining and use of these resources.

HOW THE DURATION OF THE SUPPLY MAY BE EXTENDED.

The extension of the supply of our more important mineral resources is absolutely essential to the future welfare of the nation. How to accomplish this is a problem demanding the consideration of the best science and statesmanship the country affords.

First of all is the prevention of unnecessary waste; and for this the individual and the State and Federal governments must cooperate.

All unscientific or inefficient use of resources is waste; and the most important element in conservation is the fact that the necessary waste of to-day may, through inquiry or research or through economic conditions, become the avoidable waste of to-morrow.

The waste of these essential resources being a matter of serious national concern, it is a proper function of the Federal Government to conduct such investigations as may be necessary to determine the nature and extent of the losses of life and resources and to indicate how they may be prevented.

The Federal Government has inaugurated and has well under way investigations into the nature and causes of coal-mine explosions, with a view to their prevention; into the character and value of our coals, and into the nature and extent of the waste in coal mining; concerning the fundamental problems of combustion, with a view to preventing waste in the use of fuels; and into the nature and extent of materials of construction, with a view to their more efficient use by the Government and the people, and to the prevention of disastrous fires. To these might be added similar investigations looking to the prevention of waste in the mining, treatment, and use of other mineral substances.

Such investigations being of service to all the people and to all the States, and being national in their purpose, may be conducted more efficiently by the General Government, as duplication in labor and cost are avoided where it would exist if the work were undertaken by the States or by individuals.

The cooperation of the States in this movement is essential as covering investigations of local problems and the enforcement of such legislation as might prove necessary in securing the fullest cooperation of the individual, who is naturally apt to consider first of all the question of immediate financial return on his investments. But the cooperation of the individual in the movement for the conservation of resources is needed, and may be counted on to the fullest extent that economic conditions will permit.

The duration of our mineral resources may be still further extended through investigations looking toward the substitution of common mineral substances for those which more rapidly approach exhaustion because of their rarity or greater importance, as, for example, the substitution of concrete for structural steel; of low-grade coals or lignite for those of higher grade; and of water power for steam.

Furthermore, in the case of certain supplies which are now being largely exported, or in the use of which waste is excessive, the duration may be extended for domestic use through such ownership or control as will prevent both sending out of the country and unnecessary waste.

Again, the prevention of waste, and hence the extension of the life of supplies, may be secured through such increase in the price of materials as will render practicable their more complete extraction and efficient use.

The miners and operators in our coal mines are both anxious to inaugurate reforms looking to greater safety and efficiency in mine operation, but the price of coal in the United States is too low to render possible many of the reforms which in other countries are successfully based on a price at the mine twice that in this country. It is believed, however, that when this situation is fully understood the American people will be ready and willing to pay whatever increase in the cost of fuel may be found necessary in order to guarantee the safety of the miner and to prevent the waste of resources, the preservation of which is no less essential to the nation's future than to its present welfare. The American consumer can regain the additional cost of the coal by handling and using it with correspondingly greater care and efficiency.

J. A. Holmes,
Secretary, Section of Minerals.

ORGANIZATION AND PROCEEDINGS OF THE NATIONAL CONSERVATION COMMISSION.

ORGANIZATION AND PROCEEDINGS OF THE NATIONAL CONSERVATION COMMISSION.

On June 8, 1908, the National Conservation Commission was created by the President. The President's letter to those designated to serve on the commission is as follows:

THE WHITE HOUSE,
Washington, June 8, 1908.

The recent conference of governors in the White House confirmed and strengthened in the minds of our people the conviction that our natural resources are being consumed, wasted, and destroyed at a rate which threatens them with exhaustion. It was demonstrated that the inevitable result of our present course toward these resources, if we should persist in following it, would ultimately be the impoverishment of our people. The governors present adopted unanimously a declaration reciting the necessity for a more careful conservation of the foundations of our national prosperity, and recommending a more effective cooperation to this end among the States and between the States and the nation. A copy of this declaration is inclosed.

One of the most useful among the many useful recommendations in the admirable declaration of the governors relates to the creation of state commissions on the conservation of resources, to cooperate with a federal commission. This action of the governors can not be disregarded. It is obviously the duty of the Federal Government to accept this invitation to cooperate with the States in order to conserve the natural resources of our whole country. It is no less clearly the duty of the President to lay before the Federal Congress information as to the state of the Union in relation to the natural resources, and to recommend to their consideration such measures as he shall judge necessary and expedient. In order to make such recommendations the President must procure the necessary information. Accordingly, I have decided to appoint a commission to inquire into and advise me as to the condition of our natural resources, and to cooperate with other bodies created for a similar purpose by the States.

The Inland Waterways Commission, appointed March 14, 1907, which suggested the conference of governors, was asked to consider the other natural resources related to our inland waterways, and it has done so. But the two subjects together have grown too large to be dealt with by the original body. The creation of a commission on the conservation of natural resources will thus promote the special work for which the Inland Waterways Commission was created, and for which it has just been continued and enlarged, by enabling it to concentrate on its principal task.

The Commission on the Conservation of Natural Resources will be organized in four sections to consider the four great classes of water resources, forest resources, resources of the land, and mineral resources. I am asking the members of the Inland Waterways Commission to form the section of waters of the National Conservation Commission. In view of the lateness of the season and the difficulty of assembling the members of the sections at this time, a chairman and a secretary for each section have been designated, and the chairmen and secretaries of the sections will act as the executive committee with a chairman who will also be chairman of the entire commission. I earnestly hope that you will consent to act as a member of the commission.

One of the principal objects of the federal Commission on the Conservation of Natural Resources will be to cooperate with corresponding commissions or other agencies appointed on behalf of the States, and it is hoped that the governors and their appointees will join with the federal commission in working out and developing a plan whereby the needs of the nation as a whole and of each State and Territory may be equitably met.

The work of the commission should be conditioned upon keeping ever in mind the great fact that the life of the nation depends absolutely on the material resources which have already made the nation great. Our object is to conserve the foundations of our prosperity. We intend to use these resources; but to so use them as to conserve them. No effort should be made to limit the wise and proper development and application of these resources; every effort should be made to prevent destruction, to reduce waste, and to distribute the enjoyment of our natural wealth in such a way as to promote the greatest good of the greatest number for the longest time.

The commission must keep in mind the further fact that all the natural resources are so related that their use may be, and should be, coordinated. Thus the development of water transportation, which requires less iron and less coal than rail transportation, will reduce the draft on mineral resources; the judicious development of forests will not only supply fuel and structural material but increase the navigability of streams, and so promote water transportation; and the control of streams will reduce soil erosion and permit American farms to increase in fertility and productiveness, and so continue to feed the country and maintain a healthy and beneficial foreign commerce. The proper coordination of the use of our resources is a prime requisite for continued national prosperity.

The recent conference of the governors, of the men who are the direct sponsors for the well-being of the States, was notable in many respects; in none more than in this, that the dignity, the autonomy, and yet the interdependence and mutual dependence of the several States were all emphasized and brought into clear relief, as rarely before in our history. There is no break between the interests of state and national; these interests are essentially one. Hearty cooperation between the state and the national agencies is essential to the permanent welfare of the people. You, on behalf of the Federal Government, will do your part to bring about this cooperation.

In order to make available to the National Conservation Commission all the information and assistance which it may desire from the federal departments, I shall issue an executive order directing them to give such help as the commission may need.

The next session of Congress will end on March 4, 1909. Accordingly, I should be glad to have at least a preliminary report from the commission not later than January 1 of next year.

Sincerely, yours,

THEODORE ROOSEVELT.

Personnel of the National Conservation Commission.

WATERS.

Theodore E. Burton, Ohio, chairman.
Francis G. Newlands, Nevada.
Jonathan P. Dolliver, Iowa.
William Warner, Missouri.
John H. Bankhead, Alabama.
W J McGee, Bureau of Soils, secretary.
F. H. Newell, Reclamation Service.
Gifford Pinchot, Forest Service.
Herbert Knox Smith, Bureau of Corporations.
Joseph E. Ransdell, Louisiana.
G. F. Swain, Massachusetts Institute of Technology.
W. L. Marshall, Brigadier General, U. S. Army, Chief of Engineers.

FORESTS.

Reed Smoot, Utah, chairman.
Albert J. Beveridge, Indiana.
Charles F. Scott, Kansas.
Champ Clark, Missouri.
J. B. White, Missouri.
Henry S. Graves, Yale Forest School.

Wm. Irvine, Wisconsin.
Newton C. Blanchard, Louisiana.
Charles L. Pack, New Jersey.
Irving Fisher, Connecticut.
Gustav H. Schwab, New York.
Overton W. Price, Forest Service, secretary.

LANDS.

Knute Nelson, Minnesota, chairman.
Francis E. Warren, Wyoming.
Swagar Sherley, Kentucky.
Herbert Parsons, New York.
N. D. Broward, Florida.
James J. Hill, Minnesota.
Geo. C. Pardee, California.
Charles Macdonald, New York.
Murdo Mackenzie, Colorado.
T. C. Chamberlin, University of Chicago.
Frank C. Goudy, Colorado.
Geo. W. Woodruff, Interior Department, secretary.

MINERALS.

John Dalzell, Pennsylvania, chairman.
Joseph M. Dixon, Montana.
Frank P. Flint, California.
Lee S. Overman, North Carolina.
Philo Hall, South Dakota.
James L. Slayden, Texas.
Andrew Carnegie, New York.
Charles R. Van Hise, Wisconsin.
John Mitchell, Illinois.
John Hayes Hammond, Massachusetts.
I. C. White, West Virginia.
J. A. Holmes, Geological Survey, secretary.

EXECUTIVE COMMITTEE.

Gifford Pinchot, chairman.
Theodore E. Burton.
Reed Smoot.
Knute Nelson.
John Dalzell.
W J McGee.
Overton W. Price.
G. W. Woodruff.
Joseph A. Holmes.

Secretary of the Commission, Thomas R. Shipp (elected by the executive committee).

At the time the National Conservation Commission was created, the Inland Waterways Commission, appointed on March 14, 1907, was reappointed. Three members were added and the commission was made the section of waters of the National Conservation Commission. The President's letter reappointing the Inland Waterways Commission is as follows:

THE WHITE HOUSE,
Washington, June 5, 1908.

The Inland Waterways Commission was appointed on March 14, 1907. It was appointed to meet the strongly expressed and reasonable demands of the people. Commercial organizations throughout the Mississippi Valley and elsewhere demanded then and still demand such improvement of waterways and development of navigation as will prevent traffic congestion and develop commerce. It is an unpleasant fact that, although the Federal Government has in the last half century spent more than a third of a billion dollars in waterway improvement, and although the demand for transportation has steadily increased, navigation on our rivers has not only not increased, but has actually greatly diminished. The method hitherto pursued has been thoroughly ineffective; money has been spent freely for improving navigation, but river navigation at least has not been improved, and there is a just and reasonable demand on the part of the people for the improvement of navigation in our rivers in some way which will yield practical results. It was for such reasons as these that the commission of which you are chairman was requested to consider and recommend a general plan of waterway improvement giving reasonable promise of effectiveness.

The preliminary report of the Inland Waterways Commission was excellent in every way. It outlines a general plan of waterway improvement which when adopted will give assurance that the improvements will yield practical results in the way of increased navigation and water transportation. In every essential feature the plan recommended by the commission is new. In the principle of coordinating all uses of the waters and treating each waterway system as a unit; in the principle of correlating water traffic with rail and other land traffic; in the principle of expert initiation of projects in accordance with commercial foresight and the needs of a growing country; and in the principle of cooperation between the States and the Federal Government in the administration and use of waterways, etc., the general plan proposed by the commission is new and at the same time sane and simple. The plan deserves unqualified support. I regret that it has not yet been adopted by Congress, but I am confident that ultimately it will be adopted.

Pending further opportunity for action by Congress the work of the commission should be continued, with the view of still further perfecting the general plan by additional investigations and by ascertaining definitely and specifically why the methods hitherto pursued have failed. To this end I ask that the present members of the Waterways Commission continue their most commendable public service. I am asking three others to join them, namely: Senator William B. Allison, of Iowa; Hon. Joseph E. Ransdell, of Louisiana, a member of the Rivers and Harbors Committee of the House of Representatives and president of the National Rivers and Harbors Congress; and Prof. George F. Swain, of the Massachusetts Institute of Technology, a recognized authority on water power. When a Chief of Engineers is appointed to succeed General Alexander Mackenzie, retired, I shall also designate him a member, in lieu of General Mackenzie, whose retirement relieves him of further duty on the commission. The commission will thus be increased from 9 members to 12.

In order to facilitate the work of the commission I shall shortly issue an executive order along the lines suggested by your findings and recommendations, directing the executive departments to give the commission access to their records and all necessary and practicable assistance in securing information for submission to the President and to Congress.

An indirect but useful result of the work of the commission was the recent conference of governors on the conservation of our natural resources, held in the White House May 13–15. I take great pleasure in repeating my public expression of indebtedness and my congratulations to the commission for their signal public service in connection with this great conference; it was an event which is likely to exert a profound and lasting influence on the development and history of our country.

Copies of this letter are being sent to each of the twelve members of the Inland Waterways Commission.

Sincerely, yours,

THEODORE ROOSEVELT.

The executive committee of the National Conservation Commission, which was also designated by the President, met in Chicago on June 19, 1908. and elected Thomas R. Shipp secretary of the commission.

The committee authorized the chairman and secretary of the commission to correspond with governors and other state officials and with national organizations concerned with natural resources. It agreed to write the governors, or representatives to be appointed by them, to participate in a meeting with the National Conservation

Commission on December 8, 1908. The date for the first general meeting of the commission was fixed for December 1, 1908. It was agreed that the executive committee should issue bulletins of progress from time to time, announcing places and dates of meetings and conveying other information of service to the commission. It was decided that in the collection of information the chairman and secretary of each section should act in behalf of the section and that the data collected should be coordinated by the chairman of the commission. By general agreement, the chairman was instructed to invite all necessary expert assistance in the preparation of special statements and reports.

The compilation of data planned by the executive committee was authorized by the following executive order of the President:

EXECUTIVE ORDER.

A national conservation commission to consider and advise the President upon the condition and needs of the natural resources of the country has been appointed by the President. The heads of the executive departments, bureaus, and other government establishments are hereby instructed to secure, compile, and furnish to the said commission all such information and data relevant to its work as the commission may from time to time request, and as may be respectively within the lawful powers of such departments, bureaus, and government establishments to secure, compile, or furnish, and not inconsistent with express provisions of law.

THEODORE ROOSEVELT.

THE WHITE HOUSE, *June 8, 1908.*
(No. 809.)

Under authority of this executive order, the conservation commission undertook the making of an inventory of the natural resources of the United States, in cooperation with the executive departments of the Government, state officers, and with national organizations. General supervision of the compilation of material was placed in the hands of Mr. Henry Gannett, whom the President assigned to assist the commission in its work.

The work of the commission was greatly aided by the rapid appointment of state conservation commissions, which now number thirty-five.

In addition to the cooperation of state and federal agencies, the national organizations rendered valuable assistance. These organizations named conservation committees to act in cooperation with the national commission, which now reach a total of forty-one.

The first meeting of the National Conservation Commission was held in the Library of Congress, Washington, beginning December 1 and ending December 7.

Its sessions were devoted to the discussion of the inventory of natural resources, presented by the chairman and secretaries of sections, and to the preparation of the report of the National Conservation Commission to the President, which was unanimously adopted.

The report of the commission was presented to the joint conservation conference, which met in Washington December 8–10, at which, conferring with the National Conservation Commission, were 20 governors of States and Territories, personal representatives of 11 governors and governors-elect, members of 26 state conservation commissions, and presidents and representatives of 60 national organizations.

Supplementing the report, the summaries of the four sections of the commission were presented and thoroughly discussed by the governors and the conferees, after which the committee on resolutions, consisting of the governors, ex-governors, and governors-elect who were present, united in resolutions, which were unanimously adopted and which are submitted with the report of the commission. The verbatim proceedings of the joint conservation conference are also submitted with this report.

THOMAS R. SHIPP,
Secretary to the Commission.

PROCEEDINGS OF THE
JOINT CONSERVATION CONFERENCE.

PROCEEDINGS OF THE JOINT CONSERVATION CONFERENCE.

WASHINGTON, D. C., *December, 8, 9, 10, 1908.*

GENERAL MEETING.

TUESDAY AFTERNOON, DECEMBER 8.

The Joint Conservation Conference was called to order in the Belasco Theater at 4.15 o'clock p. m., December 8, by Gifford Pinchot, chairman of the National Conservation Commission. Dr. Edward Everett Hale, chaplain of the United States Senate, pronounced the invocation, the audience joining with him in repeating the Lord's Prayer after he had read the following:

INVOCATION—DR. EDWARD EVERETT HALE.

Bless the Lord, O my soul. O Lord, my God, Thou art very great. Thou art clothed with honor and majesty. He maketh the winds His angels. He laid the foundations of the earth, that it should not be removed forever.

Thou sendest the springs into the valleys: Thou waterest the hills from Thy chambers. The earth is satisfied with the fruit of Thy works.

Thou causeth the grass to grow for the cattle and herbs for the service of man. Thou renewest the face of the earth. Thou givest their meat in due season. Thou openest Thine hand. They are filled with good.

The glory of the Lord shall endure forever. The Lord shall rejoice in His works.

Mr. PINCHOT. Mr. President, ladies and gentlemen, the meeting of governors at the White House last May, out of which this joint conference sprang, considered the natural resources of our country as the foundations of our prosperity. The conservation of these resources is clearly necessary for our welfare as a nation, now and hereafter.

Conservation implies both the development and the protection of resources, the one as much as the other. The idea which underlies it is in harmony with the true spirit of this nation. It expresses a deep-seated national conviction, latent until it came, that we have inherited from our forefathers both an opportunity for ourselves and a duty to those who come after us. Conservation demands the use of common prudence and common foresight in dealing with the great material resources upon which our present and future welfare depends.

The essence of conservation is the application of common sense to the common problems for the common good.

Conservation is simple, obvious, and right. Therefore, of all the great movements of our recent history not one has gained so fast in public appreciation and support and not one promises such results in assuring the greatest good to the greatest number for the longest time.

This nation has 3,000,000 square miles of the richest, the most varied, and the pleasantest of the continents. That land belongs to us now, just as it has belonged to our forefathers, and as it will belong to our descendants. We have the right to use it, and we have the power to impair it. The choice is ours. We can not avoid it, and we can not delay it. That we shall choose well, this meeting is the best earnest and guarantee.

The history of a nation is written best of all in the progress and happiness of its people. But it is written also in great movements, great occasions, and great men. We are gathered here to-day in the furtherance of a great movement, on a great occasion, and in the presence of great men.

I have the honor to present to you your chairman, the President-elect.

Mr. Taft. Mr. President, ladies and gentlemen, there is one difficulty about the conservation of natural resources. It is that the imagination of those who are pressing it may outrun the practical facts.

I have been introduced as the President-elect. I am not the President-elect, except in the imagination of Mr. Pinchot.

But it gives me great pleasure, as an unofficial person, to present the President of the United States.

ADDRESS OF PRESIDENT ROOSEVELT.

The President. This audience is very kind to the setting sun, and without being the seventh son of the seventh son, I can prophesy who will be the President-elect.

But, first of all, speaking to you as a private person, Judge Taft, governors, Representatives of the States, and of the great national organizations, members of the National Conservation Commission, and you men and women, my fellow-citizens, I welcome you here, our guests, to Washington and to the work you have gathered to do. No service to the nation in time of peace could be of greater worth than the work which has brought you together.

In its essence your task is to make the nation's future as great as its present. That is what the conservation of our resources means. This movement means that we shall not become great in the present at the expense of the future, but that we shall show ourselves truly great in the present by providing for the greatness of our children's children who are to inherit the land after us. It is the largest national task of to-day, and I thank you for making ready to undertake it. If you do no more than fix the national attention upon the problem, you will yet have done well. It augurs well for our future that you are here; and it is to the credit of our country that in this matter it should take the lead among the nations of the world.

All that we are asking, gentlemen, is that the National Government shall proceed as a private business man would as a matter of course proceed. He would regularly take account of stock so that he may know just where he stands; if you find that he does not know how his outgo corresponds with his income, you will not trade with him; you would be afraid to. The same measure of prudence demanded from him as an individual, the same measure of foresight, is demanded of us as a nation. Unfortunately nations have been slow to profit by the example of every individual among them who makes a success of his business. The United States is substantially the first nation to take an inventory of its stock on hand, and it has only begun to do so in any definite way within the last few months.

Last May the governors of the States and Territories met in the White House to confer with each other and with the President upon the material basis of our national welfare. They united in a memorable declaration which should hang on the wall in every school, for every citizen who is to be a voter in the next generation should grow up accepting as axiomatic the declaration of principles promulgated by your body last spring. One outcome of the conference at which the declaration was adopted was the appointment of a National Conservation Commission, whose chief duty was to prepare an inventory of the natural resources of our country—those resources which are, in the language of the governors, the foundations of our prosperity. This report is to be used by the President in transmitting to Congress information as to the state of the Union so far as the natural resources are concerned.

The commission consists of Senators and Representatives, members of the executive departments, and public-spirited private citizens familiar with particular resources. It is wholly without funds, and it has therefore depended altogether on the public spirit of its members and the cooperation, which we were so glad to give, of the executive departments at Washington and in the several States, especially the scientific and statistical bureaus. I wish to take this opportunity to express, on behalf of the people of this country, my profound appreciation of the disinterested work—work so valuable that it could not be paid for adequately anyhow, and which, as a matter of fact, was not paid for at all, performed by the individuals in private life who have given so lavishly of their time and thought, and of their money, in forwarding this cause. This work has brought these scientific and statistical bureaus into closer and more effective cooperation than ever before, and for this reason the results will rank as by far the most useful statement of the national resources ever prepared in any country. Each bureau, without relaxing its regular work, has collected and summarized the results of its past work, and has contributed them to the commission. Having made acknowledgment to one set of men, I wish to make acknowledgment to another set of men, a special acknowledgment to the government servants, State and Nation, who have so cheerfully and successfully accepted and carried out this additional task; to the man behind the pen or the typewriter who worked extra hours, who gave up part of the holiday to which he was entitled; to his bureau chief, to his division chief, who did the same thing; to all of those who rendered a public service with no thought that it would ever be known outside that it had ever been rendered, I wish to express, on behalf of our people, my heartiest thanks. They have done a real service to the whole nation at the cost of great personal sacrifice of time and effort to themselves; and the best of it all was the admirable spirit of cooperation which characterized the whole work. They all worked together, and each was concerned, not in seeing what credit he would get out of the job, but with doing his part of the job well. That is pretty high praise, and it is a pleasant thing for an American President to be able to give it.

I am especially glad to welcome the cooperation of the States through their conservation commissions and otherwise. Such cooperation gives earnest of mutual assistance between States and nation, and mutual benefits to follow. Without it the great task of perpetuating the national welfare would succeed, if at all, with difficulty. If States and nation work for it together, all in their several fields, and all joining heartily where the field is common, we are certain of success in advance. We are concerned with the people's rights; if this means national rights, well and good; if it means States rights, well and good; we are for whatever serves the cause of the people's rights.

The national organizations concerned with natural resources, such as the great engineering societies, the National Rivers and Harbors Congress, which is now holding its fifth convention; the Southern Commercial Congress, also in session, which has made so excellent a beginning—all these and many others have joined in the work in a way to gladden the heart of every patriotic American. A special word is due the National Rivers and Harbors Congress. It is the one organization that is advocating a waterway policy and not a waterway project, and is national in its scope, for it represents practically all the friends of waterway improvement in the United States. The question of river and harbor improvements and the benefit that each will bring to the producer and consumer has, through its work, been favorably and prominently brought to the attention of the country. Prominent commercial organizations and men of character and influence throughout practically every section of the country are enlisted in the cause it represents. Its work being strictly national, and in no sense local or sectional, merits and should receive the support of our citizens.

I thank all these organizations. The results of the inventory of resources will be laid before the present conference by the National Conservation Commission. I shall not attempt to review these results further than to say that the more striking facts brought out at the conference last May are amply confirmed. These facts are sobering. No right-minded citizen would stop the proper use of our resources, but every good American must realize that national improvidence follows the same course and leads to the same end as personal improvidence—and no man is a good American if he does not think of future Americans, any more than a man is a good citizen if he does not think of his children's welfare, for there isn't any man whom we despise more than the man who has a good time himself and whose children pay for it. So with the nation. That nation is contemptible that riots in abundance by wasting the heritage it should leave to the citizens that are to come afterwards. Needless waste must stop. The time to deride or neglect the statements of experts and the teaching of the facts has gone by. The time to act on what we already know has arrived. Common prudence, common sense, and common business principles are applicable to national affairs just as they are to private affairs, and the time has come to apply them in dealing with the foundations of our prosperity.

I do not believe in hysteria or sensationalism in the press or anywhere else. I would not grow hysterical or sensational in describing our condition. But neither must we allow a false security, based on conditions long since passed away, to blind us, to prevent us from seeing the facts and applying common sense to the situation they disclose. The purpose of the inventory was and is to give the facts—not to create alarm, but to take stock of what we have, and so to lead to the necessary action for its preservation and increase. Our natural resources are so related that the use of one affects the use of all the others. This is especially true of our waterways. Every man, woman, and child within our borders has an interest in them through navigation, power, irrigation, or water supply, or through all four. Every man, woman, and child in the Union has his or her welfare vitally concerned with some phase, or with several phases, of the conservation of our water supply. We have neglected our waterways more than any other natural resource, and we must put an end to that neglect. The Inland Waterways Commission has told us how.

First, prepare a comprehensive plan for inland waterway development along the lines pointed out by the commission. Such a plan must consider every use of the waters; it must put the interests of all the people in advance of any private interests whatsoever. Gentlemen, you applaud that, but I want you to act on the principle that you are applauding, and you will find it a great deal harder than to applaud it, because, mind you, the special interests include not merely and not principally interests of special individuals but interests of special localities; and any of you who do not know what it is to try to get through a scheme for the general good that seems not to pay heed to the interests of a special locality have an eye-opening experience before you; and that whether you are engaged in trying to improve the right rivers without wasting your money in improving unnavigable creeks, or whether you are trying to get proper navy-yards properly supported instead of having the money wasted on navy-yards which have the one defect of being totally useless. I got some applause for that statement, but not very much really hearty applause from people who live by the creeks or near the navy-yards to which I allude. Now, gentlemen, seriously, remember that the chance to make the waterway improvement what it must be made lies in our resolutely refusing to pay heed to anything but the great common interest. If you dissipate the improvements throughout the country on the ground that each congressional district shall have its share, you had better abandon the project from the beginning. I want you to have a comprehensive plan formulated by a national commission, because I want to see that plan genuinely national in its scope, conceived in a spirit that will make it general for the use of the whole Union. That plan must consider every use of the waters, and its preparation should begin at once. We need to have a comprehensive plan. That does not mean that we should not begin the work now. Begin the plan. But there are certain pieces of work which we already know will fit into any right plan that is produced. For these pieces of work plans have already been approved. Our previous policy of procrastination, delay, and fitful and partial action has borne its perfect fruit. Our waterways are deserted, and in return for our vast expenditures we have to show the expenditure itself and no navigation. The people are ready for a change. Let us have it, and have it at once. If we can pay the cost from current revenue, let us do so; if not, let us issue bonds. I always favor paying out of the current revenue anything that we can properly pay. I am exceedingly proud of the fact that during the seven and a quarter years that I have been President we have had on the whole a net surplus of income over expenditure of about $100,000,000, in spite of the fact that we paid $50,000,000 outright for the Panama Canal; and during these seven and a quarter years we have reduced the interest-bearing debt, slightly reduced taxation, and have paid all the expenditures made necessary by the policies upon which we have embarked, while at the same time saving up on an average some $15,000,000 a year. A pretty good showing! I would not on any account go into the business of issuing bonds to pay for anything that was not of permanent and national good. I hope it will not be necessary in this case; but if it is necessary, then, as this is a great permanent enterprise for the permanent national good of our children, it is all right to issue bonds so that the enterprise may go ahead. I am glad you cheered enthusiastically, but I want you to be just as enthusiastic about disregarding local and special interests.

The work, therefore, should begin at once; but there must not be the slightest recklessness or waste of money. No work whatever should be undertaken that has not been thoroughly examined and fully approved by competent experts, and these competent experts do not look at things exactly as if they were enthusiastic citizens of the neighborhood. Above all, not one cent should be expended to satisfy special interests, whether of a business or of a locality, or promote any man's political fortune. This is too large a business to be handled in such a way. We must approach it from the point of view of the national interest, under the guidance of the wisest experts in engineering, in transportation, and in all the uses of our streams. Forests and waterways can not be separated in any successful treatment of either. Forest protection and river development must go hand in hand. The three things which should be done without any further delay are, therefore: First, to provide for a comprehensive waterway development; second, to begin at once on work already planned that will surely fit into the larger plan; third, to provide amply for forest protection against fire, against reckless cutting, against wanton or reckless destruction of all kinds, and as a prime incident of this third provision to secure without delay the Appalachian and White Mountain national forests.

ADDRESS OF GOVERNOR GEORGE E. CHAMBERLAIN, OF OREGON.

Mr. TAFT. I have the honor of presenting Governor Chamberlain, of Oregon, to continue the discussion.

Governor Chamberlain spoke as follows:

Mr. Chairman and gentlemen, on the 3d day of October, 1907, the Inland Waterways Commission, at a meeting on board the steamer *Col. A. Mackenzie*, the President of the United States being present and presiding, it was decided to call a conference on the general subject of the conservation of the natural resources of the nation. The commission thereupon prepared a formal letter to the President, giving their reasons for such conference, and asking him in case of concurrence in their views to issue a call for the same. The next day, in a magnificent address delivered by him to the Deep Waterway Convention at Memphis, the President announced his intention to call the conference, and on the 13th day of November he issued invitations to the governors of the States and Territories to meet at the White House May 13-15, 1908, the conferees to comprise in addition to the governors three advisers to be selected by each, the Senators and Representatives in the Sixtieth Congress, the members of the Inland Waterways Commission, and representatives of certain national organizations dealing with natural resources.

The conference was had at the appointed time and place and was largely and enthusiastically attended. Later, carrying out the purposes of the conference, the President appointed a National Conservation Commission, organized in four classes, to consider the resources of water, forestry, land, and mines, and invited the governors to appoint state commissions to consider and report upon the condition of the same resources in the several States and Territories. This meeting has been appointed for a conference of the national and state commissions, in order to assist in devising ways and means for future conservation of the natural resources of the country by appropriate legislation, national and state. The Oregon commission is here to-day, represented by the chairman, Mr. J. N. Teal, with a splendid report on the natural resources of our State, and I presume all the other States will be represented and reported upon.

I have been honored by an invitation to address you on behalf of the governors, and I have accepted with some reluctance, because I fully understand that the views of the executives of the different States may be so divergent with respect to the matters to be considered—the topography, climatic conditions, and needs of the commonwealths comprising the Union so unlike—that it would be impossible for me to voice their sentiments on a subject of such vast importance to the present and future welfare of the nation.

We are probably all agreed upon one point. Conservation of the natural resources is necessary to the well-being of our country, the protection of generations yet unborn, the perpetuation of our institutions, and cooperation on the part of state and federal authorities is essential to accomplish beneficial results. As to the means to be adopted to attain the ends desired, we may differ radically. In the outset, therefore, I disclaim any intention to be the mouthpiece of the executives of the different States in the suggestions I may make as to the steps which I believe are essential to bring about the greatest good for the greatest number. It was undoubtedly timely that the forestry and reclamation branches of the Federal Government first sounded a warning as to the wanton destruction of the forests and the resultant consequences of fuel famine, soil erosion, flood waters at certain seasons and at others an insufficient supply for domestic, industrial, irrigation, and even navigation purposes. It is questionable, indeed, if this warning, unsupported in other directions, would have been sufficient to arouse the people to vigorous action. But the distinguished President of the United States, with the energy which has characterized his whole official life, early took up the subject and on the 14th day of March, 1907, appointed the Inland Waterways Commission, not only to prepare and report upon a comprehensive plan for the improvement and control of the river systems of the United States, but upon the corelated subjects of forests and their conservation, soil erosion, and generally upon the control and uses of the navigable and other waters of the country for navigation and industrial purposes.

The conclusions reached by the forestry and reclamation departments were sustained and strengthened by the investigations of the Inland Waterways Commission. All were practically agreed that the navigability of our waterways and the maintenance of uniformity of depth and flow depended upon the tributary supply streams, and these in turn upon the protection of the forests along the watersheds and upper reaches of such tributary streams. In other words that the preservation of the forests, the distribution of water for irrigation, domestic, and industrial purposes, its uses for the generation of power, light, heat, and mining, and the navigability of the rivers were so corelated and interdependent that the consideration of means for the preservation of one meant the consideration of means for the preservation and protection of all.

The conference at the White House has gone into history as one most unique in every way, and it is hoped that much good will result therefrom. It may be safely said that even if it should fail to bring about united and harmonious action upon the part of all the States, it has sounded a warning as to the necessity of resource conservation and reproduction where possible, which will certainly be of lasting benefit.

The discussions which took place and the papers read at the conference were able, interesting, and instructive, covering in detail every subject allied with the natural resources of the country, and furnished most valuable information for the guidance of subsequent investigators. No particular recommendations, however, were made for legislation either by Congress or the state legislatures to safeguard and protect our resources. That duty will probably devolve upon the present conference of the national and state commissions, and it is to be hoped that both patriotism and wisdom may characterize the deliberations of the conferees here assembled, to the end that a course may be mapped out which will meet with the approval of the whole country.

From the earliest days of the Republic the public lands, agricultural and mineral, arid, and semiarid, the waters on and under the earth, and all the resources of sea and land have been given away with a most wanton and reckless prodigality, until much that is most valuable and essential to national strength has gone into individual or corporate ownership.

As a result, magnificent resources that should have remained under government control for the use and enjoyment of the whole people have been dissipated and uneconomically administered to the enrichment of the few and the impoverishment of the many. The forests of the country, on the mountains at the headwaters of many of the navigable streams, as well as in the valleys have been denuded until now the date can almost be named when, if present methods be pursued without reforestation, there must inevitably be a lumber famine with all that such a condition entails; the coal mines are being exhausted, with an ever-increasing fuel demand, natural oils and gases are being used extravagantly and wasted wantonly, as though the supply were inexhaustible; soil erosion is taking place so rapidly by the denudation of the forests that vast areas of agricultural lands are being washed into the navigable waterways, impairing the navigability of these important avenues of commerce; the increased and increasing demands for iron and steel seriously threaten the exhaustion of the mines; and until now no step has been taken to call a halt to wasteful extravagance or to safeguard to present and future generations the little of these resources that remains. I do not underestimate the creative and inventive genius of our people, but it is no answer to the charge of wasteful extravagance in the use of our magnificent resources to say that substitutes for them all may be found whenever the necessity arises. That is not the history of other countries and of other peoples who have ruthlessly squandered the gifts of a beneficent Providence.

A partial inventory was made and an account of stock taken at the last conference, and it would be out of place at this time to indulge in detail, because the national and state conservation commissions are now engaged in making a complete inventory of all natural resources.

The question, it seems to me, which ought to engage the attention of the present conference is, what policy ought to be adopted for the future with respect to the conservation of the natural resources of the country?

One of two policies must be adopted in order to succeed, and it must be either (1) national or (2) state.

Whatever policy is adopted, it must be entered upon with a vigorous determination, a strong hand, and under intelligent direction.

1. And first as to a national policy.

As to the authority and jurisdiction of the Federal Government over the undisposed-of portions of the public domain there can be no question. There the power of Congress is unquestionably supreme with respect to the soil, the mine, the forest, and the streams tributary to the navigable waterways and their use, certainly in so far as such use might interfere with navigation.

Again, the Federal Government, under the interstate-commerce clause of the Constitution, has jurisdiction over the navigable waterways of the country. About this, too, there can be no question.

In the exercise of jurisdiction over the navigable waterways, how far can Congress or the courts go in the matter of the control of streams which, though not navigable, are nevertheless tributary to the sources of supply, and so affect the uniformity of the flow of waters in the navigable highways?

In the case of The United States *v.* Rio Grande Dam and Irrigation Company (174 U. S., 690), the court discussed this question in connection with the appropriation of water for irrigation and other purposes as affecting the navigability of a river, and in the course of the opinion said:

> Although this power of changing the common-law rules as to streams within its dominion undoubtedly belongs to each State, yet two limitations must be recognized:
>
> First. That in the absence of specific authority from Congress a State can not by its legislation destroy the right of the United States as the owner of lands bordering on a stream to the continued flow of its waters, so far at least as may be necessary for the beneficial uses of the government property.
>
> Second. That it is limited by the superior powers of the General Government to secure the uninterrupted navigability of all navigable streams within the limits

> of the United States. In other words, the jurisdiction of the General Government over interstate commerce and its natural highways vests in that Government the right to take all needed measures to preserve the navigability of the navigable water courses of the country, even against any State action. It is true there have been frequent decisions recognizing the powers of the State, in the absence of congressional legislation, to assume control of even navigable waters within its limits to the extent of creating dams, booms, bridges, and other matters which operate as obstructions to navigability. The power of the State to thus legislate for the interests of its own citizens is conceded, and until in some way Congress asserts its superior power and the necessity of preserving the general interests of the people of all the States, it is assumed that State action, although involving temporarily an obstruction to free navigability of a stream, is not subject to challenge.

And again in the same case the court said:

> It does not follow that the courts would be justified in sustaining any proceeding by the Attorney-General to restrain any appropriation of the upper waters of a navigable stream. The question is always one of fact, whether such appropriation substantially interferes with the navigable capacity within the limits where navigation is a recognized fact. In the course of the argument this suggestion was made, and it seems to us not unworthy of note, as illustrating this thought.
>
> The Hudson River runs within the limits of the State of New York. It is a navigable stream, and a part of the navigable waters of the United States, so far at least as from Albany southward. One of the streams which flows into it and contributes to the volume of its waters is the Croton River, a nonnavigable stream. Its waters are taken by the State of New York for domestic uses in the city of New York. Unquestionably the State of New York has a right to appropriate its waters, and the United States may not question such appropriation, unless thereby the navigability of the Hudson be disturbed. On the other hand, if the State of New York should, even at a place above the limits of navigability, by appropriation for any domestic purposes, diminish the volume of waters, which, flowing into the Hudson, a navigable stream, to such an extent as to destroy its navigability, undoubtedly the jurisdiction of the National Government would arise and its power to restrain such appropriation be unquestioned; and within the purview of this section it would become the right of the Attorney-General to institute proceedings to restrain such appropriation.

Numerous other cases might be cited to show that Congress has not only jurisdiction of the navigable waterways, but over the tributary streams as well, so as to prevent their use to the detriment of the navigability of the rivers they supply, and can even resume control of waters appropriated by a State for domestic purposes to the destruction of the navigability of a stream.

If this power and jurisdiction be recognized, may it not be insisted that it is within the powers of Congress to enact a uniform code, not only to safeguard the waters tributary to the navigable waterways against such diversion or obstruction as may destroy navigation, but also to provide for the distribution of such waters for beneficial use in the reclamation of the arid and semiarid lands of the country? For surely the time will come, if it is not already at hand, when the appropriation and diversion of the waters of many of the nonnavigable waters of the country for purposes of irrigation and generation of power for industrial and other purposes will seriously impair, if not destroy, the navigability of streams emptying into the Mississippi, the Columbia, and other great rivers of the country.

My purpose in this discussion is to call attention to the powers which Congress unquestionably has, and to others which, in my opinion, it has as an incident to those expressly granted. If the position assumed is correct, Congress has jurisdiction over many of the most valuable resources of the country, and why may not a law be passed creating an interstate conservation commission, authorizing them to work in connection with the departments of Government now having jurisdiction over the public lands, the forests, navigation, reclamation, and kindred subjects; making appropriations for the purchase of deforested lands in the Appalachian Range and elsewhere, with authority to reforest them, empowering them to exercise the right of eminent domain in such cases as might be necessary; authorizing the adoption of rules for the distribution of the waters of all streams tributary to the navigable waterways, and particularly those which are interstate?

Such an act would vest in the National Government jurisdiction over by far the larger part of the work of resource conservation, and would create a central administrative system which would result in great and lasting good and be more effective than any other system.

But it may be asked, Why may not the States exercise the powers herein suggested as likely to be better performed by the National Government?

To this I answer:

First, the States, as a rule, do not seem disposed to act for the preservation of their natural resources, either with respect to the land owned by them or by the exercise of their police power. There are, however, some notable exceptions to this rule.

Second, even in cases where the States have legislated with reference to the subject of the distribution of waters, whether from interstate or intrastate streams, there is such a lack of uniformity in legislation, as well as in judicial interpretation, that it is difficult, if not impossible, to determine the rights of individual citizens.

It is well known how unpopular was the policy of national forest creation in its inception in all the States. The range user as well as the small settler along the edges of the forests had come to feel that he had a right by prescription to use as he saw fit the unsold portion of the public domain. I myself was of the number to oppose the policy, but that opposition was the result of the lack of information as to the corelation of water conservation, soil erosion, flood, and drought, and the uniform distribution of waters for reclamation of the semiarid regions of the West. The movement, I assure you, now meets my hearty approval.

The unpopularity of the forest reserve is gradually giving way to acquiescence and approval, and all opposition, I am sure, will vanish when the rules for its administration can assume the order and method of a code, and people come to understand better the objects and purposes underlying it all.

Who doubts for a moment that State effort along these lines would have entirely failed, and that but for the persistent, indomitable, and intelligent effort of Mr. Gifford Pinchot, who deserves a very warm place in the hearts of his countrymen, even national effort would have come to naught?

But the difficulties that beset state control can be better illustrated by reference to the distribution of waters for irrigation purposes, particularly where the rights of citizens of different States along the upper and lower stretches of interstate navigable waters and their tributaries are involved.

To the full enjoyment of these rights there should be a uniform code governing both the distribution and use of waters, and an administrative system that can reach across state lines and enforce by proper proceedings all rules and regulations.

The National Irrigation Congress, held at Boise, Idaho, in September, 1906, realizing the difficulties in the way of regulating the distribution of waters along such streams, appointed a committee of expert irrigationists to examine into the matter and report to the next congress. This was done at Sacramento, Cal., the next year, and the committee reported amongst other things as follows:

> If there is to be any protection of priorities across state lines it should be by federal administrative system, corresponding in character to that needed for the establishing and protection of rights within a State.
>
> While it is true in the administration of water rights upon interstate streams by different States the right of appeal to the federal courts exists, that remedy is expensive, slow, and unsatisfactory. A decision of a court, once rendered, remains fixed, and only settles the particular question involved in the case, while conditions surrounding irrigation on either side of the state line are constantly changing, and the use of water for irrigation rapidly growing.

While it is true that some of the States have adopted fairly good laws governing the distribution of water for irrigation and other purposes, yet even in these there is a lack of uniformity and a conflict of judicial interpretation. A few instances might serve to show the difficulties of an equitable adjudication of water rights on interstate streams. Bear River begins in Utah, flows into Wyoming, crosses again into Utah, returns to Wyoming, then into Idaho, and empties into Great Salt Lake. Lands are being irrigated from its waters in each of the States through which it flows, and each State has a different law.

Lesser Snake River crosses the boundary line between Colorado and Wyoming four times. Adjudications as to the rights of water users in Wyoming are not heeded in Colorado and vice versa, and there is no authoritative administrative system.

The Arkansas River is another instance. It rises in the Rocky Mountains, flows for 300 miles in Colorado, crosses into Kansas, traversing it for 310 miles, enters Oklahoma, and empties into the Mississippi on the eastern boundary of Arkansas. A suit was recently instituted by the State of Kansas against the State of Colorado to determine the rights of the citizens of the two States with respect to the waters of this river. It is safe to predict that the final determination in this suit can not and will not settle finally the rights of all the parties, and some sort of interstate regulation will eventually be necessary.

Other instances might be cited, but these are sufficient to illustrate the difficulty which besets state regulation and control of waters for irrigation and other purposes.

There are again other cases where a stream has its source in one State and its waters are used for irrigation and power purposes in another; the latter State has no power or authority, if the necessity should arise, to go into the former and construct storage reservoirs, no matter how valuable they might be. I would not for a moment be understood as claiming that Congress has any power, jurisdiction, or authority to disturb rights to water which have become vested through national or state laws.

On the contrary, I insist that such rights should be protected and will be promoted by the course here suggested for national control and administration. It is in the interest of these rights as well as for those yet to accrue that radical and immediate action should be taken. Who could have foreseen when the Constitution was adopted, or even a quarter of a century ago, the change that has taken place in the semiarid regions through the distribution of water? The beginning has only been made, and the prediction may safely be hazarded that, by the construction of dams and storage reservoirs and the enactment of laws for the proper distribution of water for reasonable and beneficial use, hundreds of thousands of acres of land which to-day are considered worthless will in the next quarter of a century be reclaimed and will furnish homes for thousands of sturdy men and women. It is to protect the men of the present day and age and their descendants in the enjoyment of their vested rights against the men of the future and those of the future against the unreasonable demands of the present that federal jurisdiction and legislation is here suggested. With the federal authorities in control of the undisposed of portions of the public domain in the several States, including the forests within the reserves, and the mines and minerals therein situate, the navigable waterways with their tributary streams both for controlling their use to maintain a uniform flow for the purposes of navigation and the distribution of waters for irrigation purposes as an incident to the maintenance of the navigability of the rivers, and in control as well of deforested areas owned and to be purchased for reforestation, there is no doubt that a policy of federal administration can be formulated that will do more for the preservation and protection of our natural resources than is possible to be done by the States acting separately. But cooperation by the States will still be necessary to accomplish the highest results, and in what I have suggested it is with the idea that such a movement would have the hearty cooperation of the state authorities.

Second, as to the policy of state administration.

I have pointed out some of the difficulties in the way of administration on the part of the States, of a portion at least, of our natural resources. There is no question but that federal administration and control would be more effective, and yet I realize that jealousies between the States themselves, and fear of federal encroachment upon the rights of the States, will make it difficult to agree upon a proper course of legislation. The work in hand is so important, not only to us of the present, but to future generations, that we ought to be able to lay aside all jealousies, and endeavor in a spirit of the loftiest patriotism to reason together and formulate if possible a policy of administration that is best for all.

Before the older States realized the value of their forests, their waterways, their mines and minerals, they had allowed all to slip from their hands and into private ownership. The same thing is now going on in the younger States and soon there will be left nothing to conserve of what we received from our forefathers as a magnificent heritage. Some course ought to be mapped out now for our future course and conduct.

If a national administrative system does not meet with approval, then let it be state. The conflicting interests of the States, the different conditions which prevail in the humid and semiarid regions, in soil, in climate, in topography, and finally in laws and judicial interpretation, will render the enactment of a uniform code a task of great difficulty. It can not be done here and now, but the initial steps may be taken for the appointment of commissioners from the different States to confer together and agree if possible upon a code for submission to the different state legislatures.

But whether the policy for the conservation of our resources be national or state, there should be hearty cooperation on the part of both the national and state governments, for without it all effort must fail.

To you gentlemen of the East, the North, and the South—to you gentlemen from every section of our country in control of the Federal Government, we of the West promise our best efforts in the work of conserving all the natural resources of all the States for the benefit of all the people.

ADDRESS OF MR. TAFT.

Mr. President, ladies, and gentlemen, the first thing I would like to say is in confirmation of what Governor Chamberlain has said as to the debt that the public owe to Mr. Gifford Pinchot. President Roosevelt and Mr. Pinchot have brought about an unprecedented condition of affairs. They have gone into the States and brought the governors here, and they have created by that very fact a public opinion and a public interest in this great subject that I think could have been created in no other way.

To Mr. Pinchot's energy, I am sure President Roosevelt can testify, and everyone can testify who has had anything to do with Mr. Pinchot in playing a part in the movement that he is conducting.

How many parts of the speeches that have been delivered Mr. Pinchot has written I am unable to testify for others. But I can say that when he desires your services you might as well surrender.

Unfortunately it was not given to me to be present at the meeting of the governors last May, and I did not have the benefit of the information which was so generously spread before those who were present at that feast of reason and flow of soul. I did hear from that conference one expression that it seemed to me was singularly apt, and that has come in for criticism since, and that is the twilight zone of federal jurisdiction, an expression which I think an admirably correct one for describing something that will certainly present itself in the working out of this problem.

The truth is that the overwhelming necessity presented by President Roosevelt in his inspiring address for our doing something to conserve our natural resources is going to put us to a new test of the practical character of our system of government. It is going to involve the question whether, with the changing conditions, with the closer relations, and the interdependence of the various parts of this country, our National Constitution will furnish the means of meeting that necessity. Now, I have no doubt that it will. I have no doubt that it will, because I see the effect of it already on Democratic minds.

If it is true, as doubtless it is, that the forests and their continuance have a very direct effect upon the uniform navigability of streams, then the right of the National Government to go into reforestation is not very far removed from a constitutional demonstration.

Another reason why the Constitution should be construed, without straining it, to give to the National Government as large powers as possible in this direction, is that the plan to meet the emergency must be a comprehensive plan. It must be a plan covering the entire country, and the financial resources of no State are sufficient to carry out the plan as it ought to be carried out. I quite agree that there will be many instances in which it will be impossible even for a Democrat converted to federalism to give us federal jurisdiction within the States, and therefore that it is necessary to have cooperation on the part of the States. But nothing could have made that more possible than to summon the chief executives of the States into such a novel conference as that which met last May and which is met again this month—not, my dear friends, that it was intended to set a fire under Congress, but only that the information should be widespread and come down to the people, not only through federal tributaries, but also through the chief executives of the States.

I had some notes that I was going to read, but the truth is they contained so many expert statements that I am afraid you might suspect their authorship, and so if you will excuse me from going into a civil-service examination on the subject of waterways and water and where it conceals itself and how it ought to be treated, I shall content myself only with the statement of my deep sympathy with this movement and with my purpose, should the electors of the various States hit upon a suitable candidate, to do everything I can to carry on the work so admirably begun and so wonderfully shown forth by President Roosevelt.

I can not take my seat either without speaking in as strong terms as possible of the value of Governor Chamberlain's paper, in discussing the really difficult constitutional questions that are presented and the liberal and judicial and nontraditional spirit in which he has treated them.

One more subject and I am done. I concur in full in what the President has said in respect to the necessity of carrying out projects completed in their plan and which will fit into the general plan, and also in what he has said about the issuing of bonds. While it is true, as he said so forcibly, that the man who does not remember his children is worse than an infidel, it is also true that where a system can be devised by which the children shall meet and pay their portion, there is no reason why these little fellows who are growing up should not have a burden provided for them that will keep them under proper self-restraint. Now, I have no compunctions on the subject of issuing bonds, if the debt which is to be contracted ought to be met by bonds. I think we can sometimes overdo the business of what ought to be distributed expenses out of current income. There might be a reason for taking off taxation and reducing the income and meeting the expenditure by bonds for what are proper permanent expenses; and sometimes it takes as much courage and involves as much real public interest to issue bonds for a purpose for which bonds ought to be used as it does to pay as we go. In other words, it is a mere question of economic policy, and the mere fear of a criticism that an administration has issued bonds ought not to prevent us from doing justice to ourselves and to posterity.

Ladies and gentlemen, if the real power behind the throne consents, I declare this meeting adjourned.

(Thereupon, at 5.15 o'clock p. m., the meeting adjourned until Wednesday morning at 10 o'clock.)

CONFERENCE SESSIONS.

WEDNESDAY MORNING, DECEMBER 9.

The Joint Conservation Conference was called to order at 10 o'clock a. m. in the Red Room of the New Willard Hotel by Chairman Gifford Pinchot.

The CHAIRMAN. Gentlemen, in calling together the first joint conference for the consideration of the conservation of the natural resources of this country, I have no statement to make further than to say it seems best for the National Conservation Commission to place before you at once, so that you may at the beginning be aware of its contents, the report which it has drafted for submission to the President. This report, since it goes to the President, is necessarily a confidential communication, and therefore no copies have been printed for circulation. It will be read to the conference, without objection, as the first order of business to-day. Governor Blanchard, of Louisiana, will read the report, but Doctor Van Hise has asked me to recognize him for a preliminary statement before Governor Blanchard begins the report.

Doctor VAN HISE. It seems to me the commission should have some information as to the manner in which this report has been prepared.

Last spring the executive committee held a session in Chicago at which various lines of investigation were discussed and laid out to be pursued during the summer. Advantage was taken of the fact that the President had directed the various scientific bureaus of Washington to cooperate with the commission and to furnish all necessary information. As a result of that direction on the part of the President, the commission called upon the various bureaus in Washington to make investigations of the various resources of the country, especially with reference to their amount, with reference to the rate of exploitation, the increase of exploitation, and to give estimates as to the probable time they would last, provided the future tendencies continued at the past rate.

Therefore, when the commission gathered together last week we had before us a series of papers, prepared mainly by the experts of the bureaus at Washington, but some of them also prepared in cooperation with the state organizations and with the various national associations.

During four days those data were presented to the commission. They constituted the base of the pyramid of which the report of the commission is the apex. In those reports are found the facts upon which the commission's findings are based. Without that base, it might be thought that the commission's report was not justified, but in this matter we ask suspension of judgment in case of doubt until you may see the data and the facts which these experts have presented to us as substantiating the conclusions which the commission has reached. It would not have been possible to have accomplished so much as has been done had it not been for the services of these experts, and indeed these papers, when published, will be the most important part of the report of the commission. They of course can not be read this morning—they will constitute a book when published—and yet they will furnish the basis on which States and citizens may act.

Now a report drawn up through one week of work, based upon such data as have been furnished the commission, will be necessarily imperfect, imperfect by omission as well as otherwise, but so far as it goes the commission think it is sound and they present it as a first approximation to an adequate statement of this subject, in the hope that it may advance this movement for conservation.

REPORT OF THE NATIONAL CONSERVATION COMMISSION.

The **CHAIRMAN**. Gentlemen, it gives me great pleasure to now introduce Governor Blanchard, of Louisiana, who will read the report to which Doctor Van Hise has just referred.

Governor **BLANCHARD**. Mr. Chairman and gentlemen, the report which I am about to read has been explained to you by Doctor Van Hise, and is a compilation of a vast amount of material in the way of inventory taking of the natural resources of our country which has been going on since the President appointed the National Conservation Commission in June of the present year. This report is the result of the indefatigable labors of the Conservation Commission and of the special commission appointed by it for the purpose of preparing the report itself.

[The report in full as read will be found on page 13.]

The **CHAIRMAN**. Gentlemen, the suggestion of the commission to this joint conference for the consideration of this material is that the specific subjects—minerals, lands, forests, and waters—should be presented to the joint conference either by the chairman of the section or some member of the section chosen by him. In the belief that that plan would meet with your approval, and acting on behalf of the commission, I have invited Senator Flint to present to you more in detail the subject of minerals. After his presentation, if that be the pleasure of the meeting, the matter will be open for general discussion, with the single qualification, if I may be allowed to make it on behalf of the conference, that the governors be given the right of way. After the governors have spoken, the discussion will be entirely open.

Senator **NEWLANDS**. Mr. Chairman, before this subject is entered upon I would like to make a suggestion regarding the question of inland waterways. In conversation with Senator Frye, who is chairman of the Committee on Commerce in the Senate, the committee which has jurisdiction over harbors and rivers, I inquired whether a hearing before that committee could be secured during this week, and he replied that he would be glad to meet the pleasure of the conference either upon Thursday or Friday of this week. I present the matter now, in order that this conference may take the proposition under consideration and come to some determination regarding it.

In this connection it may be well to state that the Inland Waterways Commission, which was appointed by the President over a year ago, or pretty nearly two years ago, is now a section of the National Conservation Commission, the chairman of that section being the Hon. Theodore E. Burton, chairman of the Rivers and Harbors Committee of the House. That commission, which is purely a commission appointed by the President without statutory sanction, simply in aid of his power to make recommendations to Congress regarding legislation, entered upon an inquiry and examination and visited the different sections of the country and inspected the main rivers of the country and made a general inquiry of the subject. Prior to their report I introduced in the Senate of the United States, in a tentative way, a bill based upon discussion already had in the commission, simply with a view of testing the sentiment of the country. Later on the report of the commission was made and was sent by the President to Congress.

This bill was referred to the Secretary of War for his opinion and to the Inland Waterways Commission for its opinion. The Secretary of War approved the main features of the bill, but made some suggestions which were intended to bring it more clearly within the constitutional sphere of national action. The Inland Waterways Commission also approved the main features of the bill. That bill was considered by a subcommittee of the Committee on Commerce in the Senate and was reported favorably to the full committee with certain amendments. The bill, I will state briefly, covered, first, a waterway fund of $50,000,000. Its second provision gave the President of the United States the power to cause investigations and surveys to be made, and, in aid of that power, to appoint a commission to be known as the "Inland Waterways Commission," which was to bring into coordination all the scientific surveys of the Government relating to water, including the various bureaus of reclamation, the Geological Survey, and other surveys. It then provided for the coordination of the national surveys and their collaboration in this work. It also provided for cooperation of the States and municipalities, and it provided that whenever the fund was diminished by expenditures to $25,000,000 a bond issue should be made to make up the deficiency, bringing the fund back to its original amount of $50,000,000. It also gave this commission, whenever a project was deemed feasible, the power to enter upon the work without further action of Congress.

This bill was amended in certain material particulars by the subcommittee. I will not take your time now by stating what these amendments were.

The bill was then considered in full committee, but as there was considerable difference of opinion it seemed clear that the bill could not be presented to the Senate in time for consideration at the last session. At the suggestion of the President I introduced a shorter bill providing simply for the creation of a commission without defining its powers beyond giving it the power of investigation and a small appropriation. That bill was favorably reported to the Senate by the Committee on Commerce, but unfortunately there was not time for its consideration in the closing days of Congress.

Now, I would suggest that public opinion, of course, operates powerfully upon Congress regarding these matters. These great bodies throughout the country make public opinion. Congress always follows public opinion when it is clearly ascertained upon any subject, and it seems to me it would be well, while this great and influential body of men is here, that its leading men should appeear before the Committee on Commerce in the Senate and give their views and the views of this body and the views of the various sections of the country regarding this important question and the importance of providing a sufficient fund and the importance of providing for immediate commencement and consecutive prosecution of this great work.

I would suggest that perhaps Friday morning would be the more convenient time, as this conference is to be in session Wednesday and Thursday, and that a committee be appointed by the conference for the purpose of presenting this matter before the Committee on Commerce in the Senate upon Friday, at 10.30 o'clock.

The CHAIRMAN. Gentlemen, you have heard Senator Newlands's motion—I take it to be a motion?

Senator NEWLANDS. I will make that motion; yes, sir.

The CHAIRMAN. How many members do you think should be appointed on that committee?

Senator NEWLANDS. Have you any suggestion to make, Mr. Pinchot?

The CHAIRMAN. The only suggestion I have to make is that if the Senate committee is willing, it might receive all those members of the conference who may be willing to attend on Friday morning, and that you, yourself, arrange for the presentation of the subject.

Governor BLANCHARD. If the chairman please, what is everybody's business is nobody's business. If you say any members of this conference who desire to go may go, nobody will feel specially an obligation upon himself to go. I think that the Senator from Nevada is correct in saying that there should be a committee appointed and that it be made the specific duty of that committee to attend that hearing and present these matters.

Senator NEWLANDS. I would move, then, that the conference, or as many as possibly can do so, attend the session of the Committee on Commerce at 10.30 o'clock Friday morning, and that a committee of such number as the chair deems advisable be appointed by him with a view to presenting this matter to the Committee on Commerce.

Mr. LAY. I would suggest to the chair that that motion be amended: That there be appointed on this committee a member from each State.

Senator NEWLANDS. I will accept that with this proviso: That the chairman have the power to add such others to that committee as he deems advisable.

Senator SMOOT. Mr. Chairman, it seems to me if we want to get the information before the committee of the Senate, the best way is for the chair to appoint say three men for the purpose of presenting the matter to that committee. That is what should be done. We want the information to be presented, but if one from every State here is appointed, with no one designated to present the matter, we are going absolutely unprepared. The Senate committee can not waste time. If you appoint three men for the presentation of the matter and let every representative attend who desires, you will have some result, but if it is not arranged in that way I do not believe you will accomplish anything.

Senator NEWLANDS. I accept that suggestion—that the committee shall be appointed by the chair, consisting of at least one representative from each State, and that the chair select from this committee three men who shall have charge of the duty of presenting the subject to the Committee on Commerce.

Senator SMOOT. I second the motion as amended.

(The motion was unanimously carried.)

The CHAIRMAN. The committee will be appointed at the earliest possible moment.

Without objection, I will now call upon Senator Flint to present the matter of minerals. I take pleasure now in introducting Senator Flint.

SENATOR FRANK P. FLINT, OF THE SECTION OF MINERALS, NATIONAL CONSERVATION COMMISSION.

Senator FLINT. Mr. Chairman and members, I find myself in the awkward position of not being informed that I was to present this subject until a very late hour last night, when there was a meeting of this section of the commission. I have attended the various meetings and listened to the various papers that have been prepared, and can only in a general way present the matter to you here to-day.

The report read by Governor Blanchard shows clearly what has been accomplished, not only by this section of the commission, but the entire commission, and as my time is very limited and I am able to remain here but ten minutes more, I will just call to your attention in a general way the points brought out at this hearing.

The first thing I have to suggest is this: That an inventory has been compiled of the mineral resources of the country, which is admitted to be not what we would like in the way of a definite statement of just what we have. What has impressed us more than anything else in connection with this inventory is the lack of knowledge that we have on this subject, the importance that this commission should be continued, and that we should have a thorough inventory of the mineral resources of the country.

The very fact that we are not able to present to you a definite statement of our mineral resources seems to me a complete answer to those who say that this commission should no longer exist.

Some of the startling facts brought out in this report as to the waste of gas, where the statement is made in the report of this commission that the gas is now escaping from wells, both oil and gas wells, that could be saved, is sufficient to light all the cities of the United States with inhabitants of over 100,000, are worthy of our very serious consideration. It seems hardly possible that this great waste is going on, and yet this is the report of this commission, which has been giving careful study to this subject.

In the matter of coal, the report has been made that our coal will last until the middle of the next century. The report also contains the statement of the enormous waste that is now going on with reference to coal. The waste in all minerals produced in the United States to-day, it is estimated, amounts to $1,000,000 a day. Of all the mineral produced in the United States, one-sixth is wasted. That is the estimate of this commission. Not only has there been a great waste in the minerals produced, but a great loss of life. Not only has the loss of life been great, but it has been far greater than in other countries in the same line of work, and the trouble seems to me to be a lack of harmony between the National Government and the States in the matter of regulations for the protection of life and the waste of property. There has been considerable talk about a twilight zone, which was mentioned yesterday by President-elect Taft, which seems to me all-important in the question of the minerals that we are producing in this country and also in the matter of the loss of life in these various mining enterprises.

Yesterday Mr. Mitchell, a member of the commission, stated, as he has stated a number of times in the public press, that in his opinion the people of this nation, and especially the laboring people, would gladly favor an advance in the price of coal, so that the waste would not go on as it has in the past, and so that all those human lives would not be lost in the mining of coal, and I think that is one of the things with reference to which this conference here assembled should take radical steps, in the way of resolutions, to see if we can not bring about such a condition that the lives, which are more important than the waste of property, shall be protected by legislation, both State and national.

Another matter which this report calls to your attention is the matter of title to mineral lands, the recommendations by the mining section and the land section being that there should be a threefold title, one where the timber would be cut off under certain arrangements with the Government; second, that the surface should be farmed; and, third, that the minerals should be taken out under regulations.

Now, the condition of affairs in the country, so far as the mining laws are concerned, is as follows:

We have three different schemes for obtaining title to mineral property, viz, the coal-land laws, the lode-claim laws, and the placer-mining laws. Under the placer-mining laws we know the great frauds committed in taking up timber lands in the West, but at the same time it is difficult to frame a law that will permit placer mining and at the same time not permit the placer miner to own the surface of the ground. In other words, in placer mining as it is in the West it is necessary to take the surface or we can not have a placer mine. It seems to me there are mining claims, such as oil claims, where they might have the surface of the ground retained and then passed to the settler for farming purposes and the right given to take the oil out at the same time. Our mining laws should be changed so as to permit the various kinds of minerals to be taken out where necessary, and at the same time have the conservation of the ground that it may be used for farming.

The matter of taking out oil is another matter to which our attention has been called. Oil has been taken from the ground in various parts of this country where a mining location was made and a line of oil wells was placed along the end of the claim and then wells pumped in that way, taking the oil out of the adjoining claim. That made necessary the proposition that the man on the adjoining claim should also put down his wells. The result of this was an overproduction of oil in that place, and the oil actually lost by being pumped into large tanks, not made of iron but simply dug in the ground; and in many instances it was allowed to go to waste.

In connection with oil, another recommendation of the commission is that the oil be put to a higher use than for fuel; that coal should be used for this purpose, and our belief is that the use of oil as a fuel in our engines is a waste of the material; that if it be necessary for the future of our supply of oil, it should be conserved and put to a higher use than we are now making of it.

The coal supply is estimated to last for another century; the iron supply until the middle of the present century. With iron the statement can be made that the estimate is based only upon the class of ore they are now mining. The lower grades of ore will probably be mined in the future, and the time for the exhaustion of our mineral resources is not as near as we would be led to believe by the mere statement that iron will be exhausted in a short period. It is simply a question of the class of iron we are now mining, and not a question of the lower grades that remain yet to be mined.

Another matter called to your attention by the report of this commission is phoshate rock. There will be several talks upon this subject, and this is one of great importance to this country for the reason that this is where the mining industry comes close to the farmer. Here we find different figures presented to this commission, showing that the phosphate rock will be exhausted, as to the known supply, in about twenty-five years, and that of this phosphate rock about 40 per cent is now being exported; and the result will be that in a very short time we will find ourselves in this country in a position where we will not have phosphate to use for the fertilization of our farms; and for that reason there should be resolutions adopted, in my opinion, by this commission and the governors here assembled, looking forward to regulation of the exporting of phosphate rock. That can be done by a conservation of the mines now owned by the Government of the United States containing this rock. This subject will be treated by a number of papers, I believe, and is one of great importance.

In the matter of the question of the loss of life, Mr. John Hays Hammond, whose advice and counsel this commission has been very fortunate in having, will speak. He has talked with Mr. Mitchell, and by reason of his experience he will be able to present that subject to you in detail.

The great trouble in dealing with this mineral section is that we have to cover this entire country. Here in the East we have simply a limitation of mining to coal. Then we come to the Middle West, where they have coal and oil, and then to the extreme West, where they have minerals of all kinds. It is hard for the people in the eastern part of the United States to realize the great difference that exists in the kind of mining that goes on in the West and in the Rocky Mountains as compared with that in the coal mines in the eastern part of the country, and no one in this country is better able to present that matter from all standpoints than Mr. Hammond, who has had more experience, not only in every part of this country, but throughout the world, than anyone I know of. I will ask him to speak during the morning on the subject of labor and the differences in conditions in mining operations in this country and in other countries, as well as comparing the operations in the eastern part of our own country with those in the western part of this country.

Mr. CUTTLE, of California. Mr. Chairman, in order that this conference may have a proper record of its proceedings, I move that a committee be appointed by the chair, to be denominated a committee on resolutions, to whom shall be referred all resolutions offered before this conference, such resolutions to be referred to such committee without debate.

(Motion duly seconded, put, and carried.)

The CHAIRMAN. I will announce the committee on resolutions at the afternoon session.

Is there any discussion on this subject by any governor present? The programme, which has been tentatively established—for, of course, that means this conference will modify it in any way it sees fit—provided for one-half day for the consideration of each of the subjects, and minerals is the subject for the opening session. Is there any discussion from any of the governors with reference to the subject of minerals?

A Delegate. We discuss minerals and we discuss the forests and we discuss waters, but now as to the means of getting this before the people—the propaganda and the manner of educating the people. How is that to be done?

The Chairman. The principal means is that the report of the Conservation Commission and of the June conference shall be disseminated through the Government.

Dr. William H. Black, of Missouri. May I inquire with reference to that point? Our commission in Missouri would like to have this information at a very early date.

The Chairman. That touches a point which the commission has felt keenly. The necessity for dissemination of this information at the very earliest possible moment is a serious one for our consideration. You gentlemen will understand, in the first place, this report must go to the President. It would not be proper to make it public until it goes to him and he sees fit to make it public. In other words, whatever is addressed to the President must be made public by the President, and while we have a very strong hope that the President will act in making it public immediately upon its receipt, that matter must be left to him. Any separate action which might be taken by this conference in the way of passage of resolutions which were not included in the formal report could be made public at once.

Unless there is immediate discussion the chair would suggest Mr. Hammond be called upon. I take pleasure in presenting to you Mr. John Hays Hammond.

MR. JOHN HAYS HAMMOND.

Mr. Hammond. Mr. Chairman, I hasten to relieve the apprehension of the audience, who are led by my friend Senator Flint to expect that it is my purpose to deal, as he has intimated, exhaustively with the subject of mining accidents. As a matter of fact, I have no available statistics to present upon this sudden invitation. Besides this, there is so much else of importance for discussion at this short session that I trust you will be satisfied with the general statement that I believe a very great necessity exists for improvements in the system of mining, with the view of minimizing the loss of life.

PROF. MARSTON TAYLOR BOGERT, PRESIDENT AMERICAN CHEMICAL SOCIETY.

It will be strange indeed if the science which deals with the ultimate constituents of our material universe, their combinations and transformations, could not offer any assistance in the solution of the problem as to how our natural resources may be conserved. It is chemistry that has determined the composition of those materials which make up the earth upon which we live, the atmosphere which surrounds it, and the heavenly bodies beyond. Chemistry studies the properties of the elements and their various compounds, and upon these fundamental data our industries rest.

The transformation of the raw material into the finished product consists either in changing its external form, as in wood and metal working, weaving, and the like, or there is involved a chemical change, as in metallurgy, fermentation industries, the manufacture of glass, soap, cement, chemicals, etc. Practically all of our manufacturing processes are therefore primarily either mechanical or chemical. In the production of a metal from its ores, or of indigo from coal tar, it is chemistry that points the way; and the more complex the problem the greater the dependence upon this science. In devising new processes and in the discovery of new and useful products, chemistry is again the pathfinder. The community is apt to overlook the extent and diversity of the services rendered by the chemist because of the quiet and unobtrusive way in which the work is carried out, and yet the statement in the report of the Twelfth Census of the United States is quite correct when it says that—

> Probably no science has done so much as chemistry in revealing the hidden possibilities of the wastes and by-products in manufactures. This science has been the most fruitful agent in the conversion of the refuse of manufacturing operations into products of industrial value. Chemistry is the intelligence departments of industry.

The measure of a country's appreciation of the value of chemistry in its material development, and the extent to which it utilizes this science in its industries, generally measure quite accurately the industrial progress and prosperity of that country. In no other country in the world has the value of chemistry to industry been so thoroughly understood and appreciated as in Germany. And in no other country of similar size and natural endowment have such remarkable advances in industrial development been recorded; and this, too, with steadily increasing economy in the utilization of the natural resources.

That our own Government realizes the importance of chemistry seems evident from the fact that six of our nine federal departments already maintain chemical laboratories, where they handle not only their own chemical work but also that of the Departments of State, Justice, and Post-Office, which as yet have no chemical laboratories.

Coming then to our mineral resources, in the first place, let it be kept clearly in mind that metallurgy is a branch of applied chemistry, as it is founded upon chemistry and engineering. In general it may be said that the seriousness of our mineral problem lies in the fact that these are resources that can not be renewed. It may be urged that as matter is indestructible, metals once won from their ores should not waste but accumulate. And this no doubt is partly true. It is not so with our fuels, however, for when our carbon is once burned to carbonic acid it is no longer available as fuel, until by the slow processes of vegetable life some of it is fixed in plants and gradually reduced through peat to coal again. Six times as much of our carbon is now locked up in mineral carbonates unavailable for fuel as we have in the form of coal.

The life of our mineral resources may be prolonged by the discovery of new supplies or satisfactory substitutes, by avoiding waste in mining and extracting ores, and the discovery of methods which will render low-grade or other ores available by a more complete utilization of the latent possibilities of the ore, including the recovery of all by-products, and by preventing loss of life and property from fires and explosions.

The chemist is helping in many of these lines. It is to him that we must usually turn for the production of satisfactory substitutes, for devising new processes, and for the utilization of by-products and wastes. It was the pioneer investigations of Bunsen and De Faur which pointed the way for the use of furnace gases in preheating and in other directions, such, for example, as the recent commercial manufacture of formic and oxalic acids from the carbon monoxide present in generator gas. In smelting operations the chemist must analyze the raw materials—ore, coke, limestone, etc., the intermediate products—pig iron, if steel is to be made, and the final products, including the furnace gases and slag. Without the explosives of the chemist, modern mining, as well as most great engineering works, would be impossible. After the precious metals have been extracted it is powder which stands guard over them as it does over all the accumulated wealth and property of this and other nations. On the other hand, a chemist, Sir Humphrey Davy, by his invention of the safety lamp, has done more than anyone else to protect the miners from explosions. It is worth noting that the authorities did not appeal to a chemist until all suggested engineering methods had proven powerless to avert the terrible "firing" of the mines. The new sodium dioxide compound, "oxone," may prove of value in mine accidents, for it absorbs carbonic acid with liberation of oxygen. The oxygen upon which rescuers now depend is also the result of the skill of the chemist.

At one time the waste in the oil business was enormous, as only the kerosene was saved. Now, with the exception of occasional fires and the relatively small amount sprayed into the air with escaping natural gas, and those regions where the oil is wasted by seepage from earth pits, there is very much less lost, for chemistry has not only shown how a greater yield of kerosene may be obtained, but also how all the by-products, gas, gasoline, naphtha, lubricating oils, paraffin, vaseline, coke, and so on, may be saved with considerable financial profit. Certain of these distillates are used for the production of high candlepower illumination, as in the Pintsch and Blau gas processes. Rapid development in the use of gasoline engines has developed an enormous demand for this petroleum fraction. The most promising substitutes for gasoline appear to be alcohol and the benzole from by-product coke ovens. The former of these, although giving much higher efficiency as a fuel, is still too expensive to compete with gasoline except in special cases. The latter, as our number of by-product coke ovens increases, is likely to play a more prominent part in this field.

In 1907 over 40,000,000 tons of coke, valued at nearly $112,000,000, were produced from about 62,000,000 tons of coal. Only 5,500,000 tons of this, or less than 14 per cent, was obtained in by-product ovens. About 54,500,000 tons of coal were coked in beehive ovens. This involved a waste of 148,000,000,000 cubic feet of gas, worth $22,000,000; 450,000 tons of ammonium sulphate, worth a similar amount, and nearly 400,000,000 gallons of tar, worth $9,000,000. The gases evolved in coke ovens have high calorific power. Dantin estimates that in modern ovens only 65 per cent of this is necessary to effect the carbonization. The remaining 35 per cent amounts to about 3,700 cubic feet of gas, equivalent to 420,000 calories, per ton of coke produced. As a gas engine of 1,000 kilowatt power absorbs about 3,600 calories per kilowatt, the power wasted in beehive coking amounts to over 4,000,000,000 kilowatts, or about 3,000,000,000 horsepower. We are therefore wasting enough power to establish a great manufacturing center, enough ammonium sulphate to fertilize thousands of acres, enough creosote to preserve our timber, and enough pitch and tar to roof our houses and briquette our slag and waste coal. Lignites have been found to give not only an excellent yield of gas, but also tar, oils, paraffin, and other valuable by-products. It has recently been claimed that 1 ton of dried peat can be made to yield 162 liters of pure alcohol and about 66 pounds of pure ammonium sulphate.

In 1907, 4,000,000 tons of coal were consumed in the production of 34,000,000,000 cubic feet of coal gas for heating and illumination, worth $36,000,000, in addition to over 100,000,000,000 cubic feet of water and oil gas, worth $90,000,000, or $126,000,000 worth all told.

The value of coal to the consumer depends upon its heating power, the percentage of water it contains, the amount and character of its ash and of the clinker formed, and how extensively it corrodes the grate bars. For an authoritative answer to these and similar questions, the chemist must be consulted.

The composition of furnace and flue gases has been determined by chemical analysis in smelting and other industries, and by the utilization of these gases for preheating and for the generation of power, the amount of coal consumed has been reduced, and in addition valuable by-product recovered. In gas illumination the invention of the Welsbach mantle has greatly increased the amount of light obtainable from a given weight of coal, and has correspondingly reduced the drain upon our coal resources. The conversion of carbon into acetylene through calcium carbide should also be mentioned.

As iron, according to Clarke, composes 4½ per cent of our lithosphere, the chances of our discovering other important deposits of iron ore seem far better than in the case of other metals or of coal. The development of iron alloys is a most promising field and among these we may find satisfactory substitutes for other metals now more seriously threatened with exhaustion. The production of ferrosilicon may render available certain siliceous ores hitherto regarded as unworkable.

The chief use of iron is in the construction of railroads and of buildings. In building operations concrete is helping, not only as a substitute for iron and steel, but also as a protective covering for metallic pillars, girders, and the like. The iron and steel industry rests mainly upon chemistry and is under chemical control at every point. The production of steel by the Bessemer process depends upon the combustion of the carbon and silicon of the pig iron, the heat of combustion serving to maintain the mass molten. By the utilization of what was formerly the waste heat of blast furnaces to raise steam for the blowing engines and to preheat the blast, the amount of coal necessary to produce 1 ton of pig iron is only one-quarter what it was.

The slags are now largely used for the production of cement and concrete, as fireproof packing for steam pipes, and so forth, as ballast for railroad tracks or macadamizing highways, and for building purposes, as slag brick, slag blocks, etc., while those rich in phosphorus, as from the Thomas-Gilchrist process, are extensively employed in fertilizers. In the words of James Douglas, "When all the volatile products of the blast furnace are deprived of their heat-giving property and their chemical constituents, and with the slags, as well as the metal, have returned their heat to man instead of to the atmosphere, and the slag itself has been turned into cement or some other useful article, it will be a question as to whether the pig iron is the principal object of manufacture or one of the by-products."

The safety and comfort of travel on our railroads depends in large measure upon the skill of the chemist in testing the character of the materials employed in their construction and operation. It may be only a delay from a hot box, due perhaps to a poor quality of lubricant, or it may be a disaster from the failure of a signal or headlight at a critical moment, or a breaking of an axle or locomotive part, because of steel brittle from impurities.

Chemistry has played a prominent part in copper metallurgy. The matte is now bessemerized and 70 per cent of our total product is refined electrolytically. The avoidable waste in mining copper, zinc, lead, silver, and many other metals is estimated as at least 30 per cent. But the values now locked up in the Arizona slags, the Comstock slimes, and the Anaconda tailings will sooner or later be recovered by chemistry.

Chemistry has finally pointed the way by which aluminum may be obtained cheaply and in large amount from its ores. Last year our consumption of aluminum was 8,500 tons, worth $5,000,000, the world's production for 1907 being estimated at 20,000 tons. The commercial utilization of aluminum and its alloys is writing a new chapter in our mineral industry. To appreciate what this development in aluminum means it should be recalled that the total supply of it is nearly twice as great as of iron and about eight hundred times that of copper. Aluminum is already replacing copper for certain electrical purposes. A large part of the power now generated at Niagara Falls is distributed through aluminum alloy cables. It is also used for automobile castings, for air-ship construction, and for utensils of various kinds. The use of finely divided aluminum in Goldschmidt's "thermit" process of welding and casting is an important application of one of the chemical properties of aluminum.

A good example of the economy often accomplished by chemical investigation and discovery is furnished in the case of ultramarine. Many years ago, when this was made by powdering the mineral lapis lazuli, it sold for more than its weight in gold. Now that the chemist has discovered how to make the same material from such cheap substances as kaolin, sodium sulphate and carbonate, charcoal, sulphur and rosin, the price is only a few cents per pound.

In the field of the precious metals chemistry has contributed, among other things, the cyanide and chlorination processes, through which formerly rejected low-grade ores and residues have been compelled to give up their gold. The gold production of the world between 1851 and 1907 was three times that produced between 1493 and 1850. The value of our specie, upon which every commercial transaction rests, is determined by the chemists, while the green ink used in printing our bank notes, and to which they owe the name of "greenbacks," was invented by a former president of the American Chemical Society, Dr. T. Sterry Hunt. The chemist lets nothing escape unsearched. The sweepings from mints and from the shops of workers in precious metals, as well as the water in which the workmen wash their hands, are all made to relinquish the gold or silver they contain. Even waste photographic solutions must disgorge their silver before they are released. The invention of electroplating led to the use of plated articles instead of solid ware, and thus reduced somewhat the drain upon certain of our mineral resources. The supply of platinum has been for years so limited that the price has ranged high. Chemistry has now put on the market vessels of transparent and opaque quartz, which seem likely to replace platinum for some chemical purposes.

Many other instances might be cited where chemistry has made important contributions to the economic utilization of our mineral resources, such as the carbonyl processes of Mond, for example. But there is still much to be done in improving the present wasteful methods of smelting certain of our ores, and we may look for great advances in this direction through the rapidly developing and most promising field of electro-metallurgy.

Of the various factors upon which the success of this conservation movement depends, none, in my estimation, is more important than that of awakening the producer and manufacturer to a proper realization of the value of science to our industries.

MR. A. W. DAMON, VICE-PRESIDENT OF THE NATIONAL BOARD OF FIRE UNDERWRITERS.

Mr. Chairman and fellow-conferees, it was with unusual gratification that the officers and executive committee of the National Board of Fire Underwriters, in session on the 3d instant, received through your chairman the invitation to take part in this conference. The chairman's intimation that the appointment of a committee representing the National Board of Fire Underwriters would be acceptable was at once acted upon, and the undersigned were named as such committee. We desire to express our appreciation of the honor of a representation here, and to assure you of our interest in the great work you have undertaken and in which the organization we represent will be glad to cooperate to such an extent as may properly be within its province.

In considering the waste of the national resources we can not fail to have in mind, as underwriters, the vast destruction of values by fire year by year in the United States. Your commission has admirably divided itself into sections to take cognizance of the entire subject in a fourfold view, "waters," "forests," "lands," and "minerals," indicating the intention of broad and thorough treatment. We could have desired that the diagnosis should have proceeded a step further and added "fire" as a fifth division, and we trust that what follows will make clear the desirability of some specific treatment of this branch of the subject.

The annual fire waste in the United States for the last four years was $1,257,716,955, or an average annual loss of over $251,000,000. This is a daily average loss of $689,160. It is true this period includes the San Francisco and Baltimore fires. Extending the period to ten years, the loss was $2,029,734,345, giving an average annual loss of $202,793,434, or an average daily loss of over half a million dollars ($556,091). This waste is an absolute loss of the wealth of the country. The property value destroyed by fire is gone beyond recovery. Insurance only shifts the distribution of the loss. An irrecoverable loss it still remains.

If this enormous waste and drain were unavoidable, this committee would have no mission nor function here; but much the larger portion of this loss of property is preventable. The irrefutable evidence of this is the extraordinary difference in the fire waste of European countries and the United States.

From reports of United States consuls it has been shown by our committee on statistics that the loss in six European countries for a period of five years was 33 cents per capita. The loss in the United States for the five years ending with 1907 was $3.02 per capita, nearly ten times as much.

The result in 30 foreign cities gave a per capita loss of 61 cents, as against $3.10 in the five years' average of 252 cities in the United States.

Taking the number of fires to each 1,000 population in the same cities, our committee on statistics found it to be 4.05 in the American cities, as against 0.86 for those of Europe, showing also that, in point of frequency, fires here are far in excess of those abroad.

It is to be borne in mind that the direct fire loss is not the only waste of resources—owing to the greater frequency of fires in the United States and their greater destructiveness, more expensive fire-extinguishing facilities and apparatus must be maintained here.

We may add that it has been stated that as many as 7,000 lives have been lost by fires in the United States in a single year.

The excessive difference between the fire waste of European countries and that of the United States is caused principally by—

First. The difference in the point of view and the responsibility of the inhabitants of Europe and those of the United States.

Second. The difference in the construction of buildings.

Third. The difference in the regulations governing hazards and hazardous materials and conditions, and in the enforcement of such regulations.

Referring to the first-mentioned cause of difference it may be remarked that in a portion of Europe a landlord is responsible to his tenants and neighbors for any fire loss due to his negligence, and tenants are responsible to the landlord and to their neighbors for any loss due to their negligence. In this country a whole city might be destroyed by the unmitigated carelessness of some person, and there would not be the slightest penalty incurred. In Europe wastefulness is generally viewed as indefensible and a person who has a fire is regarded in an unfriendly light, since he has endangered his neighbor's property and comfort. In this country everybody is permitted to endanger his own and his neighbor's property almost ad libitum, either by the absence of wholesome regulating ordinances or by their nonenforcement. The reckless wastefulness of our people is nowhere more apparent than in the unnecessary fire drain on their resources. Our people appear to have a very erroneous idea of fire insurance and to think that insurance payments recreate destroyed values; whereas the fact is that insurance companies are in a sense tax collectors and distributers of such taxes among those suffering loss by fire.

The difference in the ideas of thrift, in the view of responsibility to neighbors, in the perception of the real meaning of fire loss or waste, are the cause of the larger number of fires per capita in the United States, and perhaps of the larger loss per capita.

The next principal cause of our excessive fire waste is our faulty construction. Our buildings as a whole are more flimsily constructed and are larger and higher than in the countries of Europe, where the building laws are safer and better enforced.

Our statement of the third cause of the excessive fire loss in the United States, namely, the lack of regulations to govern hazards, is self-explanatory and need not be amplified in this brief address.

The National Board of Fire Underwriters, which this committee represents, devotes its energies and activities to the reduction of the fire waste and the safeguarding of property and life, and has nothing to do with rates of premium. It confines itself to matters in which fire insurance companies have a common interest and most of which also deeply concern the public.

Thus, through a committee on fire prevention, commanding the services of a corps of engineers, the cities of the country are systematically inspected by the National Board of Fire Underwriters with a view of pointing out defects in water supplies and fire department equipments, and copies of these reports, with our recommendations for improvements, are presented for the free use of the municipalities; an extensive laboratory plant is supported for the purpose of testing materials and devices of a hazardous nature entering into the problems of fire protection; a model building code has been adopted, 10,000 copies of which have been distributed to cities and towns in the United States; an arson fund is subscribed, from which over a million dollars in rewards have been offered for the conviction of incendiaries; nearly half a million of standard rules and lists of hazardous and protective devices and materials were during the past year alone circulated to the public free of charge; hundreds of thousands of copies of the rules to regulate electric installations are annually distributed, and in every way possible we have endeavored to create a sentiment which should tend to place some check upon the constantly increasing destruction of values by fire.

The committee believes that the present fire waste in this country is an unnecessary national calamity, and that to reduce it it is essential—

First. That the public should be brought to understand that property destroyed by fire is gone forever, and is not replaced by the distribution of insurance, which is a tax collected for the purpose.

Second. That the States severally adopt and enforce a building code which shall require a high type of safe construction, essentially following the code of the National Board of Fire Underwriters.

Third. That municipalities adopt ordinances governing the use and keeping of explosives, especially inflammable commodities and other special hazards, such as electric wiring, the storing of refuse, waste, packing material, etc., in buildings, yards, or area ways, and see to the enforcement of such ordinances.

Fourth. That the States severally establish and support the office of fire marshal and confer on the fire marshal by law the right to examine, under oath, and enter premises and to make arrests, making it the duty of such officer to examine into the cause and origin of all fires, and when crime has been committed requiring the facts to be submitted to the grand jury or proper indicting body.

Fifth. That in all cities there be a paid, well-disciplined, nonpolitical fire department, adequately equipped with modern apparatus.

Sixth. That an adequate water system, with proper distribution and pressure, be installed and maintained. In the larger cities a separate high-pressure water system for fire extinguishment is an absolute necessity to diminish the extreme imminence of general conflagration.

If the commission can excite the interest of the people, the States and municipalities in the unnecessary and indefensible waste by fire in this country and the remedial measures herein recommended, they may hope to have accomplished something toward diminishing, if not entirely removing, this national misfortune.

There are already signs of an awakening public opinion on this subject. Many of the governors have mentioned it in their messages to legislatures; the insurance commissioners of the various States have frequently pointed it out and urged action, and recently the public press has shown an inclination to print articles on the subject. A law is now upon the statute book in Ohio requiring textbooks to be read in the schools on the "Dangers and chemistry of fires."

As long ago as 1892 a committee of this board addressed the President of the United States on the destruction of life and property by fire. As was expected, it appeared to him a matter for state rather than national legislation; and possibly this direction may now be given it through the connection of the governors of States with your commission. With state and municipal authorities working together many of the reforms herein suggested can without question be effected, and if this presentation should result in accomplishing this, the desire of the interest we represent would to that extent be fulfilled and the welfare and prosperity of the country measurably enhanced.

This report is submitted by the special committee of the National Board of Fire Underwriters, composed of J. Montgomery Hare, A. W. Damon, C. G. Smith, George W. Babb, R. M. Bissell, R. Dale Benson, R. Emory Warfield.

MR. THOMAS F. WALSH, PRESIDENT TRANS-MISSISSIPPI COMMERCIAL CONGRESS.

Mr. Chairman, ladies, and gentlemen, the object which calls you together, the conserving of our national resources, is a question which deeply affects our nation's future. It is the part of wisdom for nations as well as individuals to pause and look the field over, take stock, so to speak, and try to see whither we are drifting. This is not only wise as regards our national resources, but is equally so of all other channels through which wealth is created, and even more so in the sphere of ethics. Thanks to a beneficent Providence, no nation has ever made more rapid progress in the creation of wealth, and, what is of greater importance, in the uplifting and bettering of humanity, than the one to which we owe loving allegiance.

In developing and creating our great wealth, it became necessary to call freely upon our natural resources. Prodigal waste went hand in hand with use until their consumption and destruction—for it is a sad fact that we destroy more than we use—became great. Sounding the alarm and submitting the question to an intelligent and truly representative body like yours of how to stop waste and conserve these natural resources was one of the wisest of President Roosevelt's many wise acts.

In reviewing the past we must not forget that conditions have materially changed. Much that we condemn to-day was regarded as lawful and right—of sheer necessity in years past. As an illustration, take the consumption of timber. The West never could have been settled without railroads. When these railroads were projected they were looked upon as hazardous ventures, and proved so for their promoters in many cases. In the early days of railroad building the Government gave help in many ways, permitting the use of timber and ties from the forests in their construction. But the end surely justified the means.

The same wise course was followed by the Government in the field of mining. I remember being in Leadville during the winter of 1878–79. The rush to that great camp had commenced. The population increased almost over night from a few hundreds to many thousands. The winter was unusually severe, and as most of the population lived in tents the death rate from exposure and pneumonia was something appalling. The rush continued until the population increased to 30,000. Shelter had to be provided for this great army of human beings. The magnificent forests that spread for miles in every direction from the town, even to the mountain slope, had to be sacrificed to house and shelter them. When comfortable homes were established, the sickness and death rate dropped to normal. Here, as with the railroads, the end justified the means. Leadville has made permanent homes for thousands of our citizens and has enriched the country by hundreds of millions of dollars. It is one of the great productive mining camps of the world to-day. It may be said in passing that if we had had a law in force at that time similar to the laws of France, requiring the planting of a tree for every one cut down, the restoration of those beautiful forests would be almost complete by this time.

The same wise and liberal policy was extended by our Government in the building of homesteads, villages, and towns on agricultural lands and in the development of coal and iron mines. The rapid growth and development of our country was in a great measure due to the encouragement and assistance extended to infant industries by our National Government.

We are apt to bewail the great consumption of national resources, forgetting the magnificent permanent assets which we have to show for it. Trees have been put to better use in sheltering human life; coal and iron has been used in changing our land from desert conditions to teeming industrial and educational activities. Nor should we forget the sturdy pioneers of our civilization and the dangers and difficulties that they had to meet and surmount.

Now, however, the time has come to call a halt to lavish prodigality in giving away the people's inheritance. The time has come to stop giving away the public domain and to devise ways and means to husband our resources. To this end there are two courses to be pursued—one is arrestation, the other development. These should go hand in hand, for one helps the other. By arrestation I mean the stoppage of the terrible wastes that are going on in the mining and using of mineral fuels, and to some extent in other materials.

To preserve public lands for agricultural purposes, for actual settlers, we must stop the awful destruction of forests by fires and prevent the acquisition of vasts tracts by greedy corporations and individuals. Let us not forget this fundamental truth, that our welfare as a nation depends upon the justice and consideration which we show for the rights of the masses. This is a truth which the rich and well-to-do should take to heart. Instead of keeping aloof from public interests and exercise of the rights of citizenship as they too often do, they should take personal share in the affairs of government and become the initiators in all great movements that aim to make life easier, happier, and better for those less fortunate than themselves, even though this lays an additional tax upon their fortunes.

The other course, which I believe we should pursue, is that of development. Development is the greatest of all conservers. It creates and brings new wealth into activity. That man is the highest kind of philanthropist who inaugurates a new and honestly conducted industry which gives steady employment to many, with good wages and just treatment. The miner who discovers hidden treasure and causes it to be added to the wealth of the nation is a public benefactor.

The reclamation of the desert wastes, the drainage of miasmic swamps, and the utilizing of their stored fertility for the support of human life in comfortable independence are the highest and best forms of conservation.

Development creates wealth, and wealth distributed to the widest possible extent and wisely used by its possessors is one of the greatest of blessings to a nation.

This development should be carried on by the Government whenever it can judiciously do so. Individuals and corporations should receive encouragement and fair treatment from both the Government and people. Although much has been accomplished in the past, there is much, very much, to be done in the years to come to keep up our established rate of progress and to meet the pressing needs of our rapidly growing population.

Well-directed development will put all of our idle powers to work. It will utilize waters that are now going to waste, and discover and bring to light new means for saving in the consumption of and the husbanding of our resources. If electricity and heat could be drawn direct from nature's storehouse; if the air we breathe, one of the greatest forces, and one of the most pliant, ductile, and efficient for all the uses of man, could be compressed by and through itself with compensating results—in a word, if nature's materials could be used without waste, these natural blessings would be useful to man in many ways now undreamed of until the end of time. Considering what human intelligence has accomplished, this is not a mere vision.

In the sphere of mining there is much that development can accomplish which will lead to conservation. It is only recently that the world has awakened to the facts about the rare minerals. What little we know of radium leads us to believe that it possesses perpetuality of power, light, and heat. To what extent the production of this miraculous mineral may aid in this conservation is a fascinating field of speculation. The ore, by the way, from which this mineral was first extracted by Madam Curée came from a mine in Colorado, yet no atom of it has ever been produced in this country. The uranium ore that has been and is now produced from this same mine is all shipped to Germany.

Vanadium is another of the rare minerals the development of which will accomplish a wonderful conservation. It is the greatest alloy ever found for the making of steel. Its use will prolong the life of steel to many times what it is now. Here again, because of apathy, ignorance, and the lack of a governmental institution of guidance, we do not produce one pound of this valuable mineral that would do so much to husband our iron resources.

Gentlemen of the conservation board, a majority of your labors will lie in the field of mining. You will not proceed far before you will find that whilst our good Government has been generous toward all the other great activities of our national life it has been strangely neglectful toward giving a helping hand to what is in many respects the greatest of all industries.

For instance, in the field of agriculture that grand man who presides over its industries has linked science to the plow. You will find a young man at the head of the Forestry Bureau who, filled with patriotic devotion, is bringing science and energy to her aid. The Geological, Reclamation, and Weather bureaus are established on high principles and are rendering great scientific service. This is true of all other departments except that of operative mining, which receives no direct aid of any kind from the National Government.

For development and conservation of our mineral resources two governmental institutes for research are necessary—one for the baser and one for the precious minerals. These should be equipped with every modern appliance and managed by a small, compact force of the best experts and scientists obtainable. These institutes should be located in fields of active mining—one, say, in Pennsylvania and the other in Colorado. They should lead, direct, and instruct in the best methods of saving life, arresting the terrible destruction and waste now going on. They should give reliable data and information for finding and treating new minerals.

The need of such institutes has been forcibly shown recently, when our Government had to borrow scientists from other countries to solve the causes of the terrific explosions in coal mines, with the horrifying loss of life. You, too, will soon see the need of such institutes to go to in your work for information and advice.

Gentlemen, I have taken up much of your time. I ask you not to throw a blanket of sleepy inactivity over these questions of great national importance. Shut out the lawbreaker and the grafter, but encourage the prospector, the homesteader, and the honest investor. Conserve the people's rights. Be just to the present, but do not forget the future. Stand for the people and make them your allies in accomplishing the good work which you have undertaken.

In closing let me express my appreciation for the heads of our departments and their assistants. I know many of them intimately, and believe that no government receives more faithful service than ours.

It has become a good deal of a habit for certain classes to hurl criticism at public men and corporations regardless of whether they are trying to do their duty or not. Honesty and dishonesty are often but the reflex of the status of the body politic. It rests with the masses to make your task easier. It is the people who can create public sentiment which will not only conserve our national resources but, what is more dear to every lover of his country, uplift and improve the standard of that priceless heritage, American citizenship.

The **Chairman**. When I said the governors would be given the right of way I expected they would take it, but they are so modest it seems I must call upon them. There are two governors in this room interested in this matter—Governor Johnson, of Minnesota, and Governor Smith, of Georgia. I will call upon Governor Johnson for an address upon the subject of minerals.

GOVERNOR JOHN A. JOHNSON, OF MINNESOTA.

Mr. Chairman and gentlemen, I am at quite a loss to know exactly how to discuss this or any other question identified with this movement. I certainly am not in a position to discuss the matter of mineralogy or mining from a technical standpoint, either as to the matter of waste or its chemistry or any other particular feature of it. If I were to say anything at all it would be to take rather an optimistic view of the situation so far as the matter of iron mining is concerned. It seemed to me, though, as I listened to the discussions of mining, both at this conference and the one held last May at the White House, that probably we got the pessimistic opinion in our heads somehow that within a very short space of time the iron resources of the country are going to be entirely exhausted. I am quite sure that is not exactly the case and that there is no immediate danger of our running out of iron. I remember in May Mr. Carnegie read a very delightful and very able paper at the White House, in which he said that the Lake Superior country, or particularly that portion of it located in Minnesota, where they originally believed they had five or six million tons of iron ore, had now, they were quite certain, a billion and a half tons of iron ore. The statisticians who are going to present figures here later during this meeting have now items from the Oliver Iron Mining Company, an institution to which Mr. Carnegie is related in at least a very small way—the Federal Steel Company—estimating now from measurement made through the diamond-drill process, that they have two and a half billion tons of ore. If the product has increased a billion tons within a year and the production has decreased from 42,000,000 tons to 26,000,000 tons in the same length of time in the same territory, it seems to me we are going to have too much iron ore in the future. At least the press so far has put too much iron in the souls of Americans because of some of the conditions which obtain.

I am gratified to be able to bring to you—and I am not here to advertise Minnesota especially—my suggestion that we are sufficiently conceited in Minnesota to think we are going to be able to provide iron for the world for a long time to come. As a matter of news, and not particularly because it is of interest, but because it is germane to some extent to your interests here, we say that a few years ago iron was first discovered in Minnesota. The conditions have been materially or completely changed in the meantime. As a matter of fact, when the Mesabi Range was first opened up no one thought the commercial ore was of great value, being what they call 60 per cent ore. Then it ran to 55 per cent ore. That is almost the standard now. Even out on the western part of the Mesabi Range they are mining very profitably 35 per cent ore, because the steel company understand the conservation of their natural resources. Because of a washing process, they raise the standard of that ore to 50 or 55 per cent for commercial uses.

The great bodies of ore which have been discovered have been made useful by the conservation of their resources. West of the Mesabi Range we are opening what they call the Cayuna Range, and the ore is in very much deeper bodies, not of so high grade, but all new. The most sanguine promoters, if I might use that term, declare that the finding of ore on the Cayuna Range will vastly eclipse the Mesabi Range; so that we have every reason to believe that within a few years we are going to develop sufficient bodies of ore to take care of all the needs of this country for the next two hundred years, and, as Mr. Cole, the general superintendent of the Oliver Mining Company, said something like a year ago, when I was talking with him about it, "We have just begun to scratch the earth." I do not say that in a spirit of boastfulness, so far as Minnesota is concerned, or so far as the National Government is concerned. It is rather a matter of humiliation to me to know that those great iron resources of the country at one time belonged to the Federal Government and later to the government of the State of Minnesota, and by reason of the lack of interest of the people in the conservation and ownership of their natural resources, they have allowed them to pass into the hands of special interests. They are there, and they belong not to the National Government, not to the State of Minnesota, except in small degree. It is very important the National Government and the state government should conserve that which they do own and see to it that it does not pass into the hands of private owners in the future. But it is a matter of humiliation that it has gone as far as it has and into the hands of private parties.

Let me say in behalf, too, of the private individuals who own it, that owning a private enterprise means the conservation of its natural resources. There is no question of the interest of the steel company in the protection and preservation of their own property, and because it is a private enterprise they will look after the details of their business much better and much closer than state or governmental enterprises are looked after. Because of the things they have done, the Federal Government and the state government, too, can learn a very valuable lesson, and that is, in all material things at least, to conduct their business on the same broad lines of business interest which characterize a successful business man in the conduct of his private affairs. When we have divorced our public business from political considerations—and I was much moved by a remark I think by the President yesterday, who said that this should not be made the vehicle for the enhancement of any political fortunes—then the situation will be more desirable. If we will use as a measure of public good, using for our own benefit and our own advantage the lessons which come to us from successful business men's enterprises, we will do much to conserve our natural resources in that particular direction.

Now, this steel company not only owns mines in Minnesota, but mines in Alabama—and when I speak of Alabama I mean the Birmingham district—and has, by reason of experience, learned to conserve natural resources; and I am quite amused, so far as the iron industry is concerned, to hear people talk about the waste.

In the Mesabi country, as a matter of fact, I want to say it is all open-pit mining, not the underground mining; that is still done somewhat on the Vermillion Range. But in the Mesabi Range, the greatest iron range in the world, it is all done by open-pit mining, just as you would strip off a quarry or a sand pit and then start to dig the open ore; and there is absolutely no waste to it at all. There is no waste in the mining in the Mesabi Range. A great waste existed a few years ago because there was no such thing as a by-product, no such thing as coal tar or gas or cement, etc., until to-day, as was suggested this morning, as in the conducting of a great many other private enterprises, those things have become of vast importance and have much to do with the profit of their enterprises.

I am not going to discuss the matter any further than to say that I do take an optimistic view of the situation.

They say while there are billions of tons of ore, possibly the grade is low. The average grade would probably run 50 per cent in that Mesabi Range. The Krupp Works in Germany do business with iron which averages 29 per cent, and if the Krupp industry in Germany uses the average standard of ore in Germany, and that average is 29 per cent, I think there is no particular alarm to be felt about Minnesota ore. But in the country generally, there is no necessity for alarm at this particular time so far as iron is concerned.

I realize iron is a different proposition from what we meet in coal, for instance, because the iron is not, after all, destroyed. It is like some of the other minerals—always with us in some form or another. Where coal is consumed it is gone forever. It is not entirely so with iron ore. We are not particularly alarmed with that particular feature of it in our country. We are interested, so far as the development of iron interests is concerned, and the conservation of the natural resources, because the conservation thereof, in my judgment, if it means anything, means the private development and private exploitation of the industry much along the line suggested by Mr. Walsh.

We say it is kindred to or interrelated with the matter of transportation, and because of the fact it is so in the Middle West, the matter is very important, because with us it is a problem of distribution rather than a problem of mining or the value of the thing itself. For that reason, because we are the greatest iron mining district in the world, because of the fact that we are interested as a mining district, we are interested in this work of an inland waterway and believe that forestry and the inland waterways are kindred and can not be separated from each other.

I believe the great problem for this conference and the great problem for the country in the future is the development of inland waterways. I believe the greatest investment this nation can make to-day, bonded or otherwise, is to construct a canal from Lake Superior to the Gulf of Mexico. It may cost $500,000,000. Estimates have been made at $400,000 a mile. A thousand miles would cost $400,000,000, practically the capitalization of a private enterprise such as the Milwaukee or Northern Pacific, and much less than the capitalization of some of the larger railway systems.

This would solve the matter of rate regulation in the interior of the country and would make unnecessary future discussions between sections or political parties as to whether federal control or state control is best, because then the matter of competition and the matter of reform or better system of transportation would solve that matter of itself, and because then, too, we would have a great route of transportation which belonged not to private enterprises, but which would always be the heritage of the people of this country not only to-day but in the future, and such a canal as I have spoken of, with lateral and spur canals, possibly, would have much to do with the conservation, in my judgment, of the fuel. I believe it would pay for itself every fifty years in the matter of the saving of fuel alone, and would pay for itself every ten or twenty years in the reduced cost of transportation to the people.

We are interested in these things and we are interested in water particularly.

Minnesota is practically the watershed of the continent. Some of you people who are further south must remember that we start the Mississippi River down your way. We have our streams and our forestry and our mines and all those things up in Minnesota, and we are interested in the public conservation of the resources of this country—forests, water, mines, and so forth.

My own opinion is that the proper conservation consists in the proper exploitation and proper development rather than to discontinue the use of it, as, for instance, in Sweden, where I believe the amount of iron ore is limited to 5,000,000 tons per year. We want all those things to use as we need them, but we must properly exploit them and properly develop them. If the work is to be done, it must be done scientifically. It has always been my opinion that this problem was not a politician's problem at all, but that it was after all an engineer's problem. I realized this morning, as I looked at this conference and as I have watched it from the time I came into this room, that the politician is going to eliminate himself from this conservation work, and that the plodder, the man of whom the President spoke yesterday, using him as a type of man, who sits at his typewriter desk and works overtime without any pay or hope of ever getting any, is the man who will have to take it up and carry it on.

I remember at the conference last year at the White House all the governors of the States were there who could be present. Some of them came in to look over the premises to see whether it was really, after all, a desirable place to live at some time in the future. Having satisfied their curiosity, a great many of them are not here now.

A VOICE. You are still here!

Governor JOHNSON. And always will be on such an occasion.

Many of their conferees, having met in the White House, were satisfied with one experience, and then the politician having satisfied the public as to himself, and having satisfied himself as to the public, so far as he was concerned, however, left the work to go to someone else, and there is not that manifestation of interest which was displayed a little while ago, but it is going to grow just the same. This movement, if I understand it, is bigger than the Government, it is bigger than the conferees, it is bigger than the conference, it is bigger than the nation itself, and I am of the opinion we will all live to see the day when history will write into its pages the greatest achievement in the record of this nation's present chief, who made possible the conference last May, and who made possible this conference, because out of it and because of the activity of the scientific men of this country will come great good for the future of our country.

As I said at the outset, I am not a pessimist, neither am I unduly an optimist. I want to say to you, however, that if you will give us, by canal or otherwise, as good a mode of transportation as Germany has, for instance, we will guarantee to furnish you all the iron that this country wants for at least two hundred years, and you can husband the resources of Georgia and Alabama and every other section of the country.

GOVERNOR HOKE SMITH, OF GEORGIA.

The CHAIRMAN. We will now have the pleasure of hearing Governor Hoke Smith, of Georgia, whom I now present to you.

Governor SMITH, of Georgia. Mr. Chairman, ladies, and gentlemen, I was not one of those who had the fortune of looking in upon the White House the first and last time Governor Johnson was there. Indeed, this is the first time I have had the opportunity of being with you.

I have felt a deep interest in the objects of this gathering and agree with Governor Johnson that among the many good things our President has suggested, perhaps no one will last longer or produce greater benefit to the entire country than the organization which is here to-day.

We heard yesterday from Judge Taft that he had a splendid speech but would not deliver it for fear someone would recognize its authorship. Unfortunately for me, Mr. Pinchot did not know I was coming, so that I have not even the prepared speech his fertile pen might have furnished, but I wish to express my very great sympathy for the objects of this organization. Great benefit must come from it.

I do not understand your work will be limited merely to the preservation of what we have. Certainly such a course should not be followed to the extent of retarding the use of the resources of our country, and we are not ready in Georgia and Alabama to stop mining just to let Minnesota, which State can not compete with our efforts, have a chance. I believe that as speedily as possible the resources of our country should be brought into active use, provided that use is made without waste.

I believe that we should study our resources, and that one of the consequences of this gathering, and this general movement taking place throughout the country aided by local conservation organization in each State, will be the more complete investigation and comprehension of the material possibilities found in each State, thereby giving a more complete knowledge throughout our entire country of what there is in each one of the States.

This movement has aroused interest in Georgia and adjoining States. We hope to bring into active cooperation quite a large number of men, not only experts employed by the State in connection with such work, but public-spirited business men, men of property who desire to know more fully than they now know just what are the possibilities within the soil and within the mountains of our part of the Union, as they learn also what may be found that is yet undiscovered in other parts of the Union.

This knowledge should stimulate the best possible use of our mineral wealth and material resources. Substitutes will be found for things now wasted by their use. Less expensive and less valuable material will be substituted in use for commodities of larger value. The resources of our nation will be conserved by that knowledge and intelligent use which will make them tell for the most when used.

I do not desire to speak of the special resources of my section. It is not necessary to tell you that my immediate section fixes the price of pig iron the world over. I will tell that to Governor Johnson. We have vast bodies of iron still undeveloped in the State of Georgia. They are not being rapidly developed because in Alabama all the ingredients necessary for the assembling of those commodities required to make steel can be brought together cheaper than in our State. The ore beds of Georgia, therefore, will wait to a large extent for future use. We are making great progress in producing a substitute for steel. We are utilizing slate and lime located side by side to make a cement of the highest quality. Plant after plant of this character is being erected producing vast quantities of Portland cement, which must in structural matters largely relieve the pressure upon our iron-ore beds.

Assisted by the study of our resources, we will find substitutes for many things now used less expensive than those now used. We will learn how to use in the best possible way what we have. Knowing what we have all over the land, conservation will come, not from a lessening of activity, but from a quickening of those forces in the best possible way, with the best results, due to the knowledge of what we have, and how to use what we have. After all, it is not the rich field, but the minds of the people of the State that make the wealth of the nation.

Along with the progress which will come from study of our resources, and an effort to conserve them, must come the better preparation of the boys and girls of our country to handle in artistic style and with the master's hand whatever either may be called upon to do. From the simple handling of the hoe in the field up to the highest mechanical skill it behooves us, as a part of the progress for which we all long, as a part of the power commercially of our nation, which we now have and which we would hand down with growing strength from generation to generation, to see that every child is taught to use his hand with a perfect skill, and we must neither yield in resources nor in capacity of our skilled artists and mechanics to Germany or to any other country in the world.

So it is, Mr. Chairman and gentlemen, we come to you from our part of the country, rich, we believe, in resources of the most varied character, bent upon studying them, bent upon seeing they are utilized in the most profitable way, not alone for the profit of the one who owns them, not alone for advancement of the commercial and financial strength of the locality where they are found, but with the common purpose that our country, our great nation, to-day, to-morrow, and hundreds of years hence, shall fill that place which our patriotism and our love assign to it—absolutely the first among the nations of the world.

RECESS.

Governor **Blanchard**. In acordance with the prearranged program for the guidance of this conference, I now move that the conference take a recess until half-past 2 o'clock this afternoon, after which these interesting discussions by the governors shall continue.

(Motion put and carried.)

(Thereupon, at 1 o'clock p. m., the conference took a recess until half-past 2 o'clock p. m.)

WEDNESDAY AFTERNOON, DECEMBER 9.

The chairman, Mr. Pinchot, called the conference to order at 2.30 o'clock p. m.

The **Chairman**. Before we take up the subject of lands, which is set on the program for consideration this afternoon, I have to announce the appointment of the committee on resolutions, according to instructions given me this morning.

The committee on resolutions will consist of governors, past, present, and future; the future governors being limited to those concerning whom we are sure there is no doubt of their being governors, and not those who may likely be governors.

The next order of business is a statement by Senator Nelson as to the subject of lands. I take great pleasure in introducing Senator Nelson.

SENATOR KNUTE NELSON, CHAIRMAN OF THE SECTION OF LANDS, NATIONAL CONSERVATION COMMISSION.

Senator **Nelson**. Mr. Chairman, ladies and gentlemen, you who were here this morning heard the joint report of the conservation commission and the part of it relating to the matter of our public lands. This question of conserving our lands in this country resolves itself into really two different heads. One relates to the conservation of the lands that are now in private ownership, conserving them against soil erosion, and also against improper use or unwise, improper agricultural methods. That part of the problem is very well covered in the special reports that will accompany this general report. This problem relates more to the care-taking by the States than the Federal Government, for the underlying principle in reference to land matters is that where land has passed out of the hands of the Federal Government, the jurisdiction of it is under the laws and regulations of the respective States. So that whatever is done in the way of conserving lands that have passed into private ownership, the problem relating thereto must be in the main worked out under state legislation and through private efforts.

Indirectly the Government can help out in this matter, at least so far as the matter of soil erosion is concerned and so far as the matter of water is concerned, by the regulation of streams, but in respect to wasteful methods of farming and in respect to these other matters that go to the deterioration and diminution of the value of the land for agricultural purposes in the main, that is a problem either for the States or for the individual citizens.

The question to which I propose to briefly call your attention is the conservation of the public lands that are still in the ownership of the Federal Government, and before I state anything on that subject I want to call your attention to what we still own.

According to the latest statistics on this subject, we had upon the first day of July last 386,873,787 acres of public land that were unappropriated and in the Government's name and not in a state of reservation. We had in addition to that 6,400,000 acres of land in Indian reservations and we had 167,976,000 acres in forest reserves. This relates to the lands that we have within the continental boundaries of the United States and does not include the Territory or district of Alaska.

The great object or purpose which we ought to have in view is to conserve these lands for the benefit of the American people. One of our great safety valves in the past, when we have been in the midst of periods of industrial stagnation and paralysis, when we have found a large army of idle men in our industrial centers and our large cities, has been the fact that many of those people who failed to get work in those industrial centers in the large cities could wend their way to the frontier and take up public land and make little homes of their own. That has been to a large extent our safety valve in the past. The question is to preserve that for future use.

I have figured out that all of the unappropriated public lands which we now have, which are not in forest or Indian reservations, fit for agricultural purposes, would amount to 2,292,000 homesteads of 160 acres each. According to the statistics, we had at the last census 6,000,000 farms of 146 acres each. If all this public land that is still in a state of reservation could be conserved and utilized for agricultural purposes, it would furnish homes to 2,292,000 homesteaders.

One of the great problems, perhaps the greatest problem, we have on hand to-day is the utilization of these lands. Fortunately, we have such a large body of lands in forest reservations. I think that is one of the most fortunate things that has occurred in recent years in respect to our public lands.

Some years ago we tried to repeal the stone and timber law under which so many of our valuable timber lands had been appropriated at a cost of not more than $2.50 per acre. While such a bill was passed in one House of Congress, it failed to pass in the other body, and as a consequence, if it had not been for the fact that so many of our lands were segregated and put into forest reservations, we would to-day have been in a far more deplorable and precarious condition in respect to our timber lands than we really are.

We are fortunate in having this large body of lands in forest reservations. These lands are in charge of our worthy chairman, Mr. Pinchot, who, as you all know, takes a pride in carrying on this great work of forest conservation and forest preservation. When we come to think of the history of how our public lands have been disposed of in the past, it is perfectly appalling. We began at the outset by selling, aside from filling certain grants to officers and men of the Revolutionary army and some of our other wars, our lands at public sale or auction, auctioning them off in large bodies to the highest bidder, and those lands that were not bid in at public sale were offered afterwards at private sale at a minimum of $1.25 per acre, and from that usage we got the terms " offered " and " unoffered " lands. Offered lands were those which had been offered at public sale, when if not so sold they could be purchased at private sale at $1.25 an acre. Land that had been offered at public sale and not sold was open to private sale, or " private entry," at $1.25 per acre.

After we had continued under this policy of selling lands first at public sale and then at private sale, the United States took another step, which was to adopt the preemption law. That, for the time being, was of great value and great assistance to pioneers, because it enabled them to get a brief period in which to raise the money to pay for their land. Originally they could go and occupy surveyed and offered land, and file a declaratory statement, in the district land office, and have a year in which to pay for the land. Afterwards that was so modified that they could occupy surveyed and offered lands and have two and one-half years after settlement to pay for it, and on surveyed lands the same period after the plats of the survey were returned to the local land office.

In addition to these methods of disposal, we got (1862) the homestead law, which, in its main provisions, has been one of the great home builders of the country; I mean one of the great instrumentalities through which our western country has been opened, settled, and developed, and, barring some defects, it is one of the best land laws that any country has ever adopted or worked under. The defect of that law was in the " commutation " provision. Under the law as first passed a settler could " enter " his homestead, and after living on it six months could " commute " by making final proof and paying the Government the price. In many cases, however, the man who made the original entry and " commuted " did not become the permanent occupant of the land; he would dispose of it at the first chance, and thus it would pass into the hands of speculators. " Commutation " was subsequently modified so as to permit " commutation " in fourteen months. At first the Land Office interpreted that law so as to allow commutation eight months after the expiration of the first six months in which they were required to settle on the land. Afterwards the Land Office abandoned that construction, and now and for some time past it requires fourteen months actual and continuous residence before commutation can be made.

But even under that modification the records will show that a large number of homesteads are commuted, and as soon as commuted and proved up and paid for they pass into the hands of speculators and middlemen who hold them simply for a rise and not for the purpose of themselves utilizing them for agricultural purposes.

In addition to these land laws which I have briefly mentioned other laws have been passed, not so beneficent. They were no doubt designed for a beneficent purpose, but in practice they worked out unsatisfactorily. We had years ago what they called the " timber-culture law." The object of that was to promote the growth of timber on the prairies of the country, but experience showed that law was almost a failure in that respect. In the Western States, where they made these timber claims, a few trees were raised on some claims, but on many timber claims you can scarcely find a tree growing. That law was repealed some years ago. After the timber-culture act came the stone and timber act, which was no doubt passed for a beneficent purpose, for the purpose of permitting the entry of stone and timber lands that were wholly unsuited for agricultural purposes, by men who actually wanted the land for their own use. But in recent years that law has been made the vehicle under which the big lumber men have been enabled to secure large bodies of our best timber lands, to such an extent that a monopoly is threatened.

Another law was the law allowing relinquishment of lands in forests and other reservations and the selection of lieu lands in other parts of the country. Some years ago Congress passed an act creating the Mount Rainier Reservation. It was largely within the limits of the Northern Pacific Railway grant, and the land was mostly worthless. A great deal of that land was of very inferior character, with little or no timber on it. The railway company was allowed, under that law, to relinquish that land and select other lands in lieu thereof, and under that law and this right the company transferred to big lumber syndicates, who selected some of the best timber lands in the Western States in lieu of the worthless Mount Rainier lands relinquished.

The stone and timber act provided in terms that the land should be sold at a minimum price of not less than $2.50 per acre. Until recently, the Land Department has been construing that to mean the maximum price, and the lumbermen or other intermediaries who secured these lands have secured the most valuable of fir and pine land for $2.50 per acre. The Land Department has recently put a new construction on the law, holding that $2.50 per acre is merely the minimum limit, and that the Government can charge a higher price in proportion to the value of the land. If that rule is enforced, it will be a great protection for us, but in order to enforce that rule the Government, through its officials, will have to investigate and examine these lands, classify them, and determine as far as they can the quantity of timber, in order to fix the price for which these lands should be sold.

In my opinion, and I speak only for myself, all our timber lands not now included in forest reservations should be retained by the Government and never sold, but the Government should retain possession of them, conserve them, and merely sell the mature timber from time to time as the necessity arises. That is the only possible way in which we can conserve our timber supply.

Now, with reference to the agricultural lands—I mean lands not covered with timber and suitable for agricultural purposes. These lands are chiefly in the western portion of our country, west of the Mississippi, in the arid or semiarid belt. Some of them can be farmed by dry farming, some by irrigation, and some of them can be farmed by careful and prudent farming by the ordinary method.

I have grown up in two frontier States, first in Wisconsin and then Minnesota, and I have noticed one thing, and that is the arid belt and frost belt seem to retire in the face of settlement. I can remember twenty-five years ago, when the earliest settlers went to the neighborhood of Minot, on the Great Northern Railroad in North Dakota. The early settlers who went there in the first instance were literally starved out by the drought. They left and moved back into the timber in Minnesota. Within the last ten years settlers have gone in there around Minot and have raised crops successfully for the last eight or ten years, and that country now is regarded as good for agricultural purposes as any part of the great State of North

Dakota. The same thing is true in the matter of frost. I can remember some eighteen or twenty years ago, when our wheat in northern Minnesota in that territory north of a line through Crookston and Grand Forks was bitten by the frost before the crop was mature. We have not had anything of that kind in recent years. Look at the conditions immediately north of us in Canada. I visited that country last summer, and to me it appears that both the frost line and the arid lines are driven westward and northward in the face of settlement.

I believe a great deal of the land that we considered useless at one time—useless at all events without irrigation—can be farmed successfully by prudent and careful methods.

I noticed as I was passing through that country that those crops of the farmer raised on summer-fallowed land looked much better than other crops. I was told by people in North Dakota that crops raised on summer-fallowed land were considered pretty sure crops, while as to the other lands they were not at all sure, on account of drought and hot wind in the summer.

My idea is that for the welfare of our people, and in order to furnish homes for our future population, we ought to save all this great region of country that has not yet been taken up under our land laws for homestead settlers only. It should all be saved for homesteads for present and future generations.

There are plans pending in Congress to make these homesteads larger. There have been plans and Congress succeeded in passing a law some years ago applying to certain localities in Nebraska, fixing homesteads at 640 acres. I believe bills are pending in Congress now for 320-acre homesteads. It may be that in one sense a 320 or 640 acre homestead intrinsically is not too much, but we must bear in mind the amount of land we still possess and the number of people who will want land in the future, and I think the wisest and safest policy, if we consider our future interests, is to limit our homesteads in all cases to 160 acres.

There is another problem. Of course, where the Government still retains ownership and control of timber lands, the problem can be easily handled by the Federal Government, but when you come to the matter of protecting our timber lands from forest fires and other damage, lands that are in private ownership and within the several States, you will find it to be a problem that appertains to the States and belongs to the police powers of the States. Our forest fires in Minnesota last fall, when one of the prosperous towns up on what we call the iron range was totally destroyed, as well as other fires we have had there, all demonstrate that one of the causes that feeds these forest fires and makes them so dangerous is refuse that is left by the lumbermen when they do their logging. I think that it is entirely within the police power of the respective States, for the protection of the lives and the property of their people, to pass laws requiring lumbermen, when they do their logging, to burn up and destroy the refuse and waste matter, just as is now required by the forestry department of the United States. But we must look to the States for that relief, and all we can do in this convention, my friends, is to give them good fatherly advice and good sensible suggestions.

I think that the two great problems or the two important questions, so far as our public lands are concerned, are, first of all, to reserve all our agricultural land for homes. In the next place, we should retain our timber lands absolutely in the Government, and sell nothing but the matured timber. In the next place—and I agree with that part of the report—it is well to segregate these different rights. The timber lands should not be sold, agricultural lands should only be sold so far as the surface goes, and the mineral rights should be held separately and disposed of separately. I am free to confess, however, in respect to that question I have some doubt. I can readily see how, in the matter of coal lands—for instance, the lignite coal lands in Dakota—it is quite practicable to give the surface right to one man and the right to the bed of coal beneath to another man, and how the two men could work in harmony and unity; but when it comes to a matter of mineral claims, such as lode claims and placer claims, then there is some question about working out the problem. As a rule, most of the lode claims are on the mountain tops and mountain sides, and very little of the land covered by those claims is fit for agricultural purposes. The same is true in reference to placer gold mines. They are generally found in the ravines and gulches and beds of rivers, land that as a rule is not of much value for agricultural purposes. So it seems to me there is necessarily no conflict, and in making up this general report I felt perfectly safe in agreeing to the general proposition. I think the commission has made a wise and judicious recommendation to the people of the United States. Bear in mind, gentlemen, we can only work out this problem completely and thoroughly by the active work of the Federal Government and by the active cooperation of the several States, as well as the individuals.

When it comes to this matter of policing our forests that are in private ownership, the great work in reference to that must be left to the States. When it comes to protecting our own forests and controlling them, the Federal Government has absolute power in the matter. When it comes to the regulation of our water supply, the Federal Government has control of all these streams so far as purposes of navigation may be concerned. Governor Chamberlin yesterday, in his speech over at the Belasco Theater, announced, in my opinion, the correct rule.

The correct rule was laid down by the Supreme Court of the United States in the Rio Grande case, and that is that even that portion of a stream which is above the head of navigation, if it be the headwaters of a navigable stream, is nevertheless, on account of its effect upon the navigability of that portion of the stream lower down, absolutely under the control of the Federal Government.

Now, gentlemen, I have in the rough stated to you how the problem appears to me. I can only say to you that as a representative of our Federal Government, here in Congress, I shall aim to the best of my ability to work along the lines suggested by this report, so far as the interests of the Federal Government are concerned; but you governors and you representatives of the several States have a greater problem even than we have, and we must rely upon you more than upon anyone else to cooperate with us in this very important matter.

I trust that while we may not all agree as to the details, yet in respect to the great general problem in hand we shall all work together as good patriotic American citizens, not only looking to our own immediate welfare, but to the welfare of the generations to come, in order that our grand country may continue to grow and prosper in the future as it has in the past.

GOVERNOR EDMOND F. NOEL, OF MISSISSIPPI.

The CHAIRMAN. This subject naturally falls into two parts, the public-land question and the agricultural question. Governor Noel, of Mississippi, has signified his willingness, on my request, to speak on the agricultural side of the question. I take pleasure in presenting to you Governor Noel, of Mississippi.

Governor NOEL. As with Governor Smith this morning, this call comes unexpectedly, and upon a topic to which I have given no recent study. In our section, especially in Mississippi, nearly all public lands, unfortunately, have passed into private ownership, leaving small basis for forest reservations. Originally our fertile soil, mild climate, and large and well-distributed rainfall made almost the whole country woodland. The forests of Mississippi contain about 120 different species of trees, consisting of numerous varieties, there being 15 of oak. The large pine forests of south Mississippi, and of hard wood in the delta, are being rapidly cleared, usually by methods unnecessarily wasteful. The chief consideration with many seems the largest delivery to mills at the smallest outlay, wholly regardless of the effect on other industries or on posterity.

Mississippi is preeminently agricultural, and with over 58 per cent of its population negroes it has a much larger proportion of its wealth and population engaged in or dependent on farming than any other State. In its early days, when the soil was fresh and fertile and much of the forests were undisturbed, almost any method of cultivation produced bountiful harvests. When the soil became thin from unchecked erosion and continuous replanting of the same crops without fertilization, it was often abandoned to gullies, and other and fresh fields obtained by destruction of their valuable timber. Warned by lessening returns for the fruits of their labor, a general effort is now being made not only to check this downward trend, but to reverse its course, and through improved cultural methods and judicious selection of plants, animals, diversification of crops, and fertilization, to fully restore the productive power [illegible] land and labor. This movement has been given great impetus by the well-considered and admirably executed measures for the conservation of our natural resources, initiated by the President and ably seconded by various worthy government officials, especially by the Secretary of Agriculture and by our chairman.

Food and clothing, the prime necessaries of life, come originally from farms. Therefore every man, woman, and child, at all times and everywhere, are directly concerned in advanced and successful agriculture. In many ways and in all parts of the Union the Department of Agriculture, through its varied activities, has become more and more helpful. By cooperation with States and their subdivisions, surveys, topographical, soil, and surface and underground water, are being made and mapped, instructing the people in the quality and capacity of their natural resources and of the most approved methods of utilization. Intelligent and successful farming and stock raising are manifested by putting land and labor to the most permanently profitable use, profitable in its broadest sense, as affecting both present and future generations. The Agricultural Department of our Government is ably supplemented by our agricultural schools and colleges and their experimental stations, where the best selections of seed, animals, and cultural methods are accurately and scientifically tested with reference to varied climatic and soil conditions. This information is disseminated in an easily understood form. Steady and rapid advances are being made in the treatment of injuries resulting to plant and animal life from all causes, some being but recently discovered.

In the South the Federal Government is extending effective and greatly appreciated help in our fight for our cattle as against the fever tick, which costs us tens of millions of dollars annually in losses to cattle; and also in our fight against our small but dangerous enemy, the boll weevil, which crossed the Mexican border about sixteen years ago, marching steadily northward and eastward through the cotton belt, never wholly abandoning territory once invaded, and carrying immense damage, if not temporary ruin, to all who do not avail themselves of the new cultural methods tested and taught by the Department of Agriculture and its cooperating agencies. Though I come from a State probably the most united as against the dominant political party, we gratefully acknowledge and cordially welcome the very effective assistance extended to us by the National Government.

About one-third in value, and one-sixth in area, of the lands of Mississippi, and considerable parts of Louisiana and Arkansas, are protected from ravages from floods by levees, which levees also aid river navigation, and are sufficient for these purposes except when extreme high water brings death and destruction to life and property. Those inhabitants and all others of our State and of many other States are vitally interested in whatever affects, especially in the Mississippi basin, the distribution and disposition of rainfall, which are materially modified by the removal or the replanting of forests. The muddier the water the more difficult it is to control and the greater is its power of erosion and of making sand bars. Careless methods of cultivation not only rob the land, through erosion, of more fertilizing properties than is consumed by crops, but also aggravate the evils and reduce the benefits of water courses. In speaking of his State, Minnesota, Governor Johnson announced that it supplied part of the waters that passed through the lower Mississippi. For water of proper quality, free from unneeded sediment, and properly distributed throughout the year, the people of the lower Mississippi Valley are exceedingly grateful, but not so for muddy floods, delivered in such volume as to defy human control. The occupants of the lower Mississippi Valley are the greatest sufferers from the sins of deforestation and of soil erosion of the whole Mississippi basin and should be fully protected from overflows of the Mississippi by the strong arm of our Federal Government, which has the entire control of the waters and the navigation of the Mississippi River.

Kind Providence has been exceedingly gracious in its bestowal of the blessings of a fertile soil, a genial climate, and well-distributed rainfall to Mississippi and other Southern States, bringing prosperity to all who make good use of their opportunity.

The whole Mexican Gulf coast, outside of lower Florida, which is really tropical, can successfully grow almost all kinds of tropical fruits. Mississippi can profitably produce nearly every kind of crop, vegetable or fruit. For farming and pasturage our lands are almost ideal. Our summers are long, with nights generally pleasant and days not excessively warm. Our winters are short and mild. When not already fertile, our lands can generally be made fertile at a moderate expenditure of time and money. Cattle can thrive throughout the year with little or no shelter, and need be fed only for a few winter months, and in some localities not at all, cane and grass there affording perennial subsistence.

My mission here is not one of speechmaking, but of listening and learning. I have gathered from some of the best posted authorities much valuable data pertaining to the value and location of our natural resources and of the best means of obtaining its benefits without unnecessary exhaustion. The most valuable service that I can render Mississippi is, directly and through various agencies, to bring its citizenship into a full and living realization of the material data affecting the extent and conservation of our natural resources, which have been so wisely and diligently collected and so admirably presented to this conference. I thank our President, the chairman of this conference, and all of those who have rendered this efficient public service, and sincerely wish them godspeed in their useful and patriotic labors.

GOVERNOR MARTIN F. ANSEL, OF SOUTH CAROLINA.

The CHAIRMAN. During the last address Governor Ansel, of South Carolina, has come into the room, and I am sure we shall be glad to hear from him. I take pleasure in presenting to you Governor Ansel, of South Carolina.

Governor ANSEL. Mr. Chairman, ladies, and gentlemen, I do not know whether my friend, Governor Johnson, is in the house this afternon or not, but it was my pleasure to be with him at the first conservation meeting that was held at the White House in May, and I want to tell him that I am one of the governors here to-day and that I am one of the governors who expect to attend these meetings in the future. It is a great pleasure for me to be at these meetings, not only a great pleasure and privilege, but it has been a great educator so far as I am concerned.

The conservation of our natural resources is something that has been in my mind for some little time, and more particularly since the first meeting was called when so much information was given to each of us of the great possibilities, the great wealth of this great country of ours. I am not a pessimist, my friends. I am an optimist, if anything, and I believe that we have the greatest country in the world: in fact, I know it. I know that our natural resources are equal to those of any of the nations of the world, and even the small State of South Carolina has tin within her borders, and it has been recently mined to a profitable degree. We have also large deposits of monazite, and I believe monazite is only found in the States of North Carolina and South Carolina.

This discussion this afternoon is on the subject of lands, if I am not mistaken. I am sorry I was not here at the beginning of this afternoon's session. The trouble with me is I can not divide myself into two or three people at one and the same time. I wanted to attend the Rivers and Harbors Congress, which is in session on the tenth floor of this building. This morning I was before the Agriculture

Committee of Congress talking about the Appalachian Forest Reserve, one of those things in which we are very much interested in our country; and I wanted to be here at the same time. My heart is in this work.

We had a great flood in August of this year and the loss of land, of ground, of soil was something enormous as the result of that one flood. While crops were devastated, while the corn was carried off, yet that was only a part and a small part of the great injury that was done to our lands by carrying them into the sea by the flood such as we had in August last. That, of course, gets back to the question of the forests and of the waters, and I have not time to discuss those questions this afternoon. I want to say that we feel down in our country a great interest in this question of the preservation and conservation of our natural resources.

Our lands, our waters, our forests, our minerals are things in which each and every State of the Union is interested, in order that we may send down to posterity that which we received from the good Lord when we came here.

I never until recent years fully appreciated that little couplet I learned as a small boy:

Woodman, spare that tree,
Touch not a single bough.

Little did I think then that the tree would become so important; so important as it is to-day in the question of forests and deforestation. Little did I think then that so much interest would be manifested in our forests, so important to our landed interests, that the tree should be protected in order that the floods would not carry away the land; that the forests being denuded would permit the silt to go down the river as it does in these large floods.

I am not here on this program to make any speech to you upon this subject, but I am here to tell you something of the interest we feel in our portion of the country in this great question that is now being discussed from one end of this country to the other. If this great conference does nothing else, my friends, than to make us think and make us act upon the knowledge that we have, these great reserves that we have an interest in, the preservation of these resources for our posterity, our children, and our grandchildren, it will have accomplished a great deal.

I for one wish to thank my friend, the chairman of this meeting, for the great interest he has manifested and shown in the great work of preserving our natural resources. I have had many communications with him upon the subject and I know that he has in his heart the interest not only of one State and another State, but all the States of this Union, in the preservation of these things which make the material wealth of our country and which are to be handed down to posterity. We live not only for ourselves, but for our children. We should preserve to them those things which are necessary in order that they may receive from us what we received from our forefathers.

I wish, therefore, this afternoon just to bid you godspeed in the great work that has been started here and to express the hope that it may be carried forward and result in the preservation and conservation of these great resources of ours in order that the country may go forward as it has been going, continuing to hold her place as the first nation of the world.

GOVERNOR N. B. BROWARD, OF FLORIDA.

The CHAIRMAN. I thought I saw Governor Broward, of Florida, come in while Governor Ansel was speaking. I know we shall be very glad to hear from him, and I now take pleasure in presenting to you Governor Broward, of Florida.

Governor BROWARD. Mr. Chairman, ladies, and fellow-citizens of the United States, I will not undertake to make a speech this afternoon, as I have been so busy since coming to Washington, attending first one conference and then another, that I fear my remarks might be so scattering on this subject, without some study, that I would fail to hit anybody or anything.

I heard a story told once that is apropos of my condition at this time. An old gentleman frequently went out squirrel hunting with his son. The old gentleman was slightly palsied, and it was his province to shake the bush and frighten the squirrel around on the other side of the limb, and the province of the boy to do the shooting. On one occasion the old gentleman had scared the squirrel around on the other side of the limb several times, and the boy had several clear shots at the squirrel but missed him every time. The old man, becoming vexed, and ammunition being scarce and costly, said: "Come here and shake the bush; let me shoot. Let me try it." The boy went over and shook the bush, and the squirrel went around on the other side of the limb, and the old man held the gun up and shook all over, and finally the gun went off and down came the squirrel. The old man said: "That is the way to shoot. That is the way to shoot." The boy said: "Well, no wonder you hit him; you aimed all over the tree."

On this occasion I would have to aim all over the tree and all over the continent, and I would rather reserve the right, if my friend will permit me, to wait until to-morrow or some other time that suits him, when I can better entertain you on this subject. I have a scattering knowledge of it or conception of it, and realize to some extent its great importance, and as I look into the faces of those who have studied it closely, and especially that of the Senator from Nevada, who, next to Mr. Pinchot, has done the greatest work along this line, I feel that the generations yet unborn will appreciate to some extent at least the great things that will be in store for them as the result of the persistent efforts of those two gentlemen who did not live entirely for themselves.

I thank you.

SUGGESTION BY SENATOR FRANCIS G. NEWLANDS, OF NEVADA.

Senator NEWLANDS. May I make a suggestion, Mr. Chairman? The last Conservation Congress emphasized the importance of cooperation between the National Government and the States upon the questions which we have under consideration. The report recently presented emphasizes the importance of cooperation. A year has passed by since the last conference was held. There has been some opportunity for state action upon this subject. I think it would be quite instructive to this conference to ascertain what action has been taken in the various States and also to discuss some method of uniform action by the States upon this subject. I have recently received a letter from the governor of my own State, Nevada, in which he expresses an earnest desire to cooperate with the National Conservation Commission in this work. He requests information and suggestions upon the subject. Yesterday I was handed a report by the Conservation Commission of Oregon. I have had no opportunity yet to look it over. That report indicated that Oregon has already taken action. This was quite a voluminous report, some 60 or 70 pages.

Let me here suggest that state action can be taken in two ways—one by the passage of a statute by the legislature, the other by executive action. Of course, it is highly important that action should be taken by the legislature of the State, because then some efficient method of action is always indicated. But where that has not been secured, or where it is difficult to secure, it is entirely within the province of the governor of any State, under the power which he has of recommendation to the legislature with regard to legislation. to call to his aid any body of citizens, and he can give such body such name as he may choose, and I would suggest that where States through their legislatures have not taken action, the governors of the various States can appoint, just as the President of the United States appointed, a conservation committee of the State, with a view to preparing a report and making recommendations to him. It will be a very fruitful method of agitating the question, of forming public opinion upon the matter, and the result will doubtless be, in every State, that the merely recommendatory commission appointed by the governor, without constitutional action and without legislative action, will ripen into legislative action which will cover the field of administration as well as the field of recommendation. I would suggest that as the governors and Representatives of the various States are called upon they say something regarding the previous action of each State upon this subject, the action which has already taken place, and the action which may be contemplated.

The CHAIRMAN. I am sure Senator Newlands's suggestion is good. I may say at the beginning that 28 of the States have appointed conservation commissions, and some 30 of the great national organizations are represented here. I, too, have before me the report of the Oregon commission. Other commissions have already prepared reports, and I am certain that the conference will be very glad indeed to hear, from either the governors or the chairmen or representatives of the state commissions, what has been done.

Senator SMOOT. Have we passed from the subject of public lands? Have we said all that is going to be said upon that subject?

The CHAIRMAN. No; the subject of public lands is still before us for discussion.

Governor ANSEL, of South Carolina: Responding to the suggestion of my friend, so far as South Carolina is concerned, we have no statutory provision upon that subject, but since the meeting of the governors last May I have appointed a conservation committee, consisting of our commissioner of agriculture, state geologist, and two other citizens, and they are to report to me, giving me the information they have in order that I may take such action in my message to the legislature as may be thought best, and I believe they have also given Mr. Pinchot data with reference to the matters upon which he desired information.

The CHAIRMAN. I would suggest in this connection that the National Conservation Commission has had a great deal of encouragement and assistance from the governors and their commissions.

HON. W. P. LAY, OF THE ALABAMA STATE CONSERVATION COMMISSION.

Mr. LAY. Mr. Chairman, as to the reports from the States and the conservation commissions appointed for the States, I have the honor of being chairman of the commission appointed for Alabama, and therefore beg to say: We prepared a report and turned it in to your honorable secretary, which report I believe you have before you. The report contains probably 50 or 75 pages and takes up the various subjects, I think, fairly well—in line with the inquiry.

We covered the ground the best we could considering the short time in which we had to work, and considering also that we had no funds at our command to aid us in the work. We found the duties very arduous, yet very interesting, and as we examined into the various subjects we could realize more and more the importance of the work.

We took up each subject in form as the inquiries were made, as the report will show. First, the land laws; second, agriculture; third, waterways; fourth, forestry, and fifth, minerals, and made as complete an inventory of each as our limited time would permit, together with recommendations as to how, in our opinion, some of these could be most economically handled—that the best and most lasting results might be obtained therefrom.

In looking into the subject we found some very interesting questions and the field large, and one that offers very great opportunity for study and research.

One of the conclusions at which I arrived was, that of all our natural resources I do not know of any that promises more results than is promised by the proper conservation, improvement, and development of our waterways. In fact, it occurs to me that the most potent factor in conserving our resources is to first conserve, improve, develop, and utilize our streams. When this is done, in my opinion, the greatest achievement in our efforts for conservation has been accomplished.

To fully appreciate why this is so, we must consider:

First. The use and benefits to which these streams can be applied.

Second. Their possibilities to contribute such benefits when they are improved so as to utilize their natural flow, and when they are improved so as to utilize their practical conserved flow.

Third. The economy and saving which they are capable of accomplishing when so improved.

CHIEF VALUE OF STREAMS.

The chief values of our streams are for navigation and for development of power; therefore, if the plans for their improvement are properly designed with due consideration for conserving both these valuable agencies of human affairs in the most minute detail, their joint development and improvement can be most economically accomplished, with the promise also of the most economic results from their joint operation.

DUAL SYSTEM.

With this end in view, it will be seen by examining our report that we recommend most heartily, for the improvement of our waterways, a dual system of navigation and water-power development, where water power is possible, together with a system of impounding or storing the flood waters of the streams in aid of such navigation and power development and the amelioration of the floods. And we recommended also, very heartily, that the Government of the United States in its improvement of our streams for navigation act in conjunction with private capital in the development of the water powers, where such water powers exist, upon such equitable terms as may be right and just, to both the Government of the United States in its efforts to improve navigation and to the riparian owners of the water-power rights.

WATER TRANSPORTATION.

The benefits of water transportation are too well known to need comment from me, hence I shall not dwell on that part of the subject.

VALUE OF POWER.

To be brief in treating on the value of power in its relations to manufacture and commerce, I shall deal principally in statistics, as compiled by Mr. W. J. Clark for the Niagara Falls Power Company.

The total value of manufactured articles produced in the United States during the year 1900 was approximately $13,000,000,000. Five million three hundred thousand wage-earners contributed their labor to produce these articles, and 11,300,000 horsepower was used for manufacturing purposes. Thus, for every wage-earner 2.13 horsepower was used to aid him in producing $2,452 worth of goods during the year. No other country employed power to an extent at all comparable with this, and also, no other country derived such great return in manufactured articles from its workers.

Russia and Spain, which stand lowest in the list of power-using countries (.15 horsepower per wage-earner), produced in value of manufactures only $440 and $361, respectively, per wage-earner. Fifteen foreign countries, including Canada, had in 1900 an average of .3 horsepower per wage-earner, of whom each produced an average of $519 worth of goods.

Pennsylvania during the year 1900 produced $1,834,790,960 worth of manufactured goods by the aid of 733,834 workers and 1,859,263 horsepower. For each wage-earner, aided by 2.54 horsepower, an average of $2,500 worth of manufactured articles was produced.

The following figures, being the statistics from which the figures in the preceding paragraphs have been taken, are of interest, as they indicate clearly the relation which exists between manufacturing progress and the use of power.

Countries.	Wage-earners.	Total horse-power used in manufactures.	Value of products.	Value of products per wage-earner.	Horse-power per wage-earner.
United States	5,308,406	11,300,181	$13,004,400,143	$2,452	2.16
United Kingdom	9,000,000	3,000,000	5,000,000,000	556	.33
Germany	10,000,000	3,400,000	4,600,000,000	460	.34
France	5,000,000	1,500,000	3,450,000,000	690	.30
Belgium	1,550,000	630,000	720,000,000	480	.42
Switzerland	600,000	320,431	300,000,000	500	.54
Austria-Hungary	4,700,000	750,000	2,000,000,000	425	.16
Russia	4,500,000	700.000	1,980,000,000	440	.15
Italy	3,600,000	900,000	1,700,000,000	472	.25
Norway	200,000	80,000	90,000,000	450	.40
Sweden	490,000	200,000	280,000,000	572	.41
Holland	460,000	130,000	245,000,000	540	.29
Spain	1,800,000	250,000	650,000,000	361	.15
Australia	550,000	460,000	500,000,000	900	.80
Japan	382,298	84,216	220,000,000	566	.22
Canada	550,000	750,000	800,000,000	1,455	1.36

POSSIBILITIES OF WATER-POWER DEVELOPMENTS.

A stream, as it applies to water power, is like a chain, only as strong as its weakest link. In figuring on the possibilities of water-power developments on an unconserved stream, we can only figure, practically, on the results obtainable from the minimum discharge of the stream, counting all in excess of this to be wasted, but in reckoning the power possibilities on our streams in Alabama, I shall show both the horsepower possible with the minimum flow and also the power possible with a practical conserved flow, from the fact that on the headwaters of our rivers, like almost all other rivers in the United States, there are found desirable reservoir sites at which reservoirs of sufficient capacity to answer all purposes can be economically constructed when compared to the benefits to be derived from them.

WATER POWER IN ALABAMA.

The following table will show the primary water power possible in Alabama, conservatively estimated:

	Horsepower.
Tennessee, with minimum natural flow	162,000
Tennessee, with practical conserved flow	396,000
Coosa, with minimum natural flow	120,000
Coosa, with practical conserved flow	360,000
Chattahoochee, with minimum natural flow	115,000
Chattahoochee, with practical conserved flow	230,000

It is probable the possible water powers on unnavigable streams will be about 10 per cent of that on navigable streams. This would give Alabama:

	Horsepower.
With unconserved streams	436,000
With practical conserved streams	1,084,000

This means that it would require, according to standard tables, 4,505,000 tons of coal per annum to produce by steam the power of these streams in their unconserved state, and 11,201,000 tons of coal per annum to produce by steam the power of these streams in their practical conserved state.

Alabama is producing to-day about 14,000,000 tons of coal per annum for every purpose. Thus it will be seen that it will take about 80 per cent of the entire production of coal in Alabama at this time to produce by steam the power of these streams that is now going to waste.

Suppose for a moment that the coal fields of Alabama were sliding down an incline and pouring off over a precipice into fathomless space at the rate of 11,201,000 tons per annum; how long would it take the people of the United States to get busy and try to stop such a waste of a God-given resource? Yet, what else are we doing when we sit idly by and let the water of these streams go to waste over a precipice, while we ourselves burn up the coal?

AID OF NAVIGATION BY STORAGE.

We have been considering in Alabama for a year or two a plan for the improvement of navigation on the Alabama River which contemplates the impounding of the flood waters on the headwaters of the Coosa River in Georgia, from which an increased discharge might be had to aid navigation on the Alabama River during low-water periods, which does not exist over sixty or ninety days at any one time, and this only occurs probably every eight or ten years.

Our studies and investigations looking to this plan of improvement are very interesting and from our present viewpoint promise splendid results, and is probably only typical of what can be done on many other streams.

The extreme low-water discharge of the Alabama River is approximately 2,000 cubic feet per second. This will give with the average slope of the river and the proper channel work, as contemplated over the shallow places, 4 feet of navigation. Six thousand cubic feet of water per second with the same width channel will give 8 feet of navigation. Therefore it follows that 4,000 additional cubic feet discharge per second from a storage system for a period long enough to bridge over the low-water stage of sixty to ninety days will make 8 feet of navigation on the Alabama River possible at all times.

Then, in addition to this, the 4,000 additional cubic feet per second, together with the natural flow of 2,000 cubic feet passing through the turbines over the rapids on the Coosa River, will give the maximum horsepower for power purposes as heretofore explained.

We find also on the headwaters of the Coosa River a number of desirable sites at which storage reservoirs can be economically constructed that will give the requisite quantity of water necessary, we think, to give these results, and at the same time the reservoirs will very materially lessen the impetuosity of the floods.

DR. CHARLES R. VAN HISE, OF THE UNIVERSITY OF WISCONSIN.

Doctor **Van Hise**. Representing the Conservation Commission of Wisconsin, I am requested, in the absence of the governor, to speak on one subject of the work of that commission which is apropos to the subject under discussion this afternoon, that of lands.

The subject to which I shall call your attention for a few moments is that of the phosphate of the soil. I select this particular subject because it shows the interrelation of the work of conservation in the several States. You may wonder why I, in Wisconsin, a State which has no phosphate deposits, should be especially interested in this subject, but the phosphate deposits is a matter in which every State is interested. Of the various elements of fertility in the soil, nitrogen, potassium, and phosphorus are the important ones. Combined nitrogen for the soil may be obtained from the atmosphere by methods which I need not discuss; potassium is present to the extent of 2½ per cent in the original rocks, and in some to three times that amount; and even if the natural concentrations be used up we shall be able, by sufficient expenditure, to use the original rocks as the source of potassium to fertilize the soil.

Phosphorus is present in the original rocks to the extent of only eleven-hundredths of 1 per cent. It is the element which is most crucial in the matter of soil fertility. Mr. Hill, at the conference last spring, told of the decreasing productivity of the grain fields, wherever the lands have been cropped for some time, not only in the Northwest, but in the various parts of the country. The most important chemical factor in the decrease is the depletion of the land in phosphate. You who are familiar with the situation in the upper Mississippi Valley may think that the wonderfully fertile lands there located have a sufficient amount of this element, and yet investigations recently made by the agricultural experiment stations of Ohio, Illinois, and Wisconsin show in these States that the element phosphorus has already been greatly reduced. So far as I know, the only quantitative studies which have been made are in Wisconsin. There Mr. A. R. Whitson has shown that the fields which have been cropped for fifty years have lost one-third of their phosphates. The director of soil work in Illinois is here to speak for the commission of that State and will supplement my statement.

There is absolutely no way of handling the land by which we can increase its content of phosphate. To increase its phosphate requires the addition of a fertilizer containing phosphorus. If the loss for the United States has been as much as one-half as much as it has been for the State of Wisconsin in the cropped fields for fifty years, a simple calculation shows the entire products of our mines at the present rate of production would be required for more than one hundred years to restore to the soils of the country their original fertility in phosphorus; and Mr. F. B. Van Horn, of the Geological Survey, who has made a careful estimate of the deposits of phosphate in Florida, South Carolina, and Tennessee, and a rough estimate as to the probable amount that may become available in the West, calculates that the supply of this element is sufficient to last for only about fifty years, even at the present rate of consumption.

Last month there was an announcement of the formation of the Franco-American Consolidated Phosphate Company, the capital of which is almost exclusively held abroad. This phosphate company has already purchased a large portion of the richest phosphate lands in Tennessee, which contain the largest supplies of phosphate of any State, with the exception of the western deposits. What is the purpose of obtaining these lands? Manifestly it is to ship our phosphates abroad to restore phosphorus to the depleted soils of Germany, France, and Spain, for all three of these countries are represented in the capital of that company. Gentlemen, it seems to me there should be a law which would prohibit the exportation of a single pound of phosphate from this country. We do not want an export duty in any case. We want prohibition. To allow our phosphates to go out of this country is nothing short of agricultural suicide.

Under modern conditions we are wasting annually enormous quantities of phosphate. A large proportion of the fertilizers produced on the farms which contain much phosphorus is allowed to wash into the streams and thence into the sea. Under our modern sewage system, by which we dump into the rivers the sewage, we are also sending an additional amount of that essential element to the sea. Here in the city of Washington to-day there is going down into the Potomac and into the sea this valuable fertilizer. Upon this point Mr. Whitson has made a rough computation and he estimates that through the sewage systems of the cities of the United States the equivalent of at least 1,200,000 tons of high-grade phosphate is lost annually. If the soil's fertility is to be retained, and upon the soil depends our food and clothing, this waste must be stopped. Of all the great questions which have come before this commission the preservation of the fertility of the soil is the most fundamental. We must in some way stop this criminal waste of our phosphates, for the amount exported is much less than the amount that is wasted by our improper methods of agriculture and sewage disposal.

Here is a great responsibility and a great opportunity for the governors of the States and the teachers of agriculture all over the country. The people must be taught to realize their responsibilities to posterity in this matter. They must be brought to understand that unless this element of phosphorus is conserved, unless soil erosion is controlled, the most fundamental of all our resources, the soil will become greatly depleted and will be able to sustain only a relatively small population.

You may ask the question, if the above statements are true, how is it that the crops grow well in China and Japan? In the densely populated parts of these countries practically all the fertilizing element produced by animals and by man goes back upon the soil. Where this is done the phosphate may be used over and over and over again and the fertility of the soil in phosphorus may be perpetually maintained.

I dwell upon this subject at some length because it seems to me to be one of the great fundamental questions before us. This is one of the questions which the commission in Wisconsin has taken up with reference to the interests of that State, but you can readily see we can not consider this matter in our State without thinking of the situation in the Southern States and in the Western States, where are to be found the natural phosphate deposits. No other subject shows more clearly how the future welfare of all the States interlock; how the nations and the States and the individuals must cooperate in conserving our natural resources.

MR. J. H. RICHARDS, PRESIDENT OF THE AMERICAN MINING CONGRESS.

Mr. **Richards**. My friends, as I stand here facing you at this moment, I am again impressed with the idea that there is nothing so certain in human life as the unexpected. I had prepared to leave your city, and was about to leave when I was requested to contribute my mite to the great thought force you are undertaking to set in motion and disseminate throughout the country from this center.

My peculiar relation to the mining thought of this nation within the last seven years is the only justification for attempting to occupy your attention even for a moment. In my efforts as president of that organization to give direction to the mining thought of this country along lines that are in harmony with the purposes of your meeting, I have been impressed with this idea, that we can not deal here with details, but only with those fundamental questions that have been implanted in the human heart from the beginning; that they may be promulgated and sent out to the American people from this important meeting.

We create nothing. We simply discover the true basis of human growth which existed from the beginning, promulgate or set it in motion, then apply it to our needs.

Ideas rule the world, and should rule it. This was impressed upon me when the ideas, implanted in the human heart from the beginning, found expression in the dawn of our country's life, when our fathers promulgated and applied to our needs the great constitutional and legal foundations upon which this country must rest for all future time. It was again illustrated, and showed how deep the roots of those great ideas are planted in American hearts, when the strength of this nation was tested, when the constitutional rights that had been established were tried, and again established and forever. As a result of that contest we came to realize, through personification of American manhood in the form of Abraham Lincoln, that we are a united nation and that we all stand equal before the law. Our country was established and preserved upon that theory. At this time the third important crisis in the history of our nation confronts us, when in order to insure our continued and stable prosperity we must develop our wonderful resources along the constitutional lines that have been laid down for us by those who have gone before.

This development must be nationalized and promulgated from this center of thought. We can then coordinate and utilize these various local resources.

I am impressed that we must send out over the country the thought that we believe the time has come when in meetings of this character we must try to direct, through cooperation, coordination, and conservation, the use of our national bounties.

Nature has been so generous in her bounties that it takes a generous heart to interpret and cooperate with her in developing our industrial possibilities, and at this time we must send out from this center thoughts that are in harmony with the idea of cooperation, coordination, and conservation, but at the same time in harmony with our constitutional and legal basis upon which our development must rest.

As president of that mining organization, these are the things that have been impressed upon me now for seven years. It has been my hope that there may be impressed upon the mining thought of the day the central point of your purpose in meeting here, and that is, all we attempt to do must rest upon the constitutional and legal basis upon which our Government is founded and upon which our national development must rest.

I have received inspiration from your chairman, and I love him for what he is to this nation; and now, since I have had the privilege of meeting his mother in this hall, I have no doubt why he is what he is.

I want to leave this one thought with you, resulting from the experience of seven years in this character of work: That we must nationalize and promulgate this idea of conservation of our natural resources in harmony with our constitutional basis, and then coordinate all of the state and local forces into one grand, harmonious whole; because I am convinced that underneath all the changing scenes of our material development there is the everlasting foundation of scientific truth. Aside from the waste of natural resources, the waste of human life must be considered—and this is a thought that was made prominent at our convention at Pittsburg—the man under ground must have the same legal and constitutional protection as the man above ground. We can not carelessly sacrifice human life longer upon the altar of industry. We must remember that the capacity of the American citizen to achieve and enjoy the fruitage of his industry is the greatest asset the nation has. And out of this great industrial development that is now just beginning to dawn upon the world there will come that moral and spiritual uplift of the American people which will be the crowning glory of American civilization.

EX-GOVERNOR NEWTON C. BLANCHARD, OF LOUISIANA.

Governor **Blanchard**. Mr. Chairman and gentlemen of the conference, I, too, like our friend who has just addressed the conference, am expecting to take my departure this evening from the city of Washington, and before I go would like to address a few words to the conference.

I have been here now for nine or ten days, hard at work with other members of the National Conservation Commission and the experts in the preparation of the report which was read this morning. It has been to me a work of great interest and instruction.

I was much pleased with the admirable address delivered before this body earlier in the day by the distinguished governor of the State of Minnesota. So optimistic, however, were his views relative to the supply of certain of the natural resources of the United States that it set me to thinking that if he be not mistaken in what he said, why has the National Conservation Commission existed at all? He told us, in direct contravention to the carefully prepared report of the National Conservation Commission—and that report is founded upon information supplied by the government experts—that there is iron ore enough in the State of Minnesota alone to last this country for centuries. The report of the commission declares that, so far as the high-grade ores now in use are concerned, the middle of the present century will see their exhaustion; and that so far as the low-grade ores are concerned (the ores which must come into use after the high-grade ores are exhausted), their exhaustion may be looked for not much later than the end of the present century.

I am informed by the Director of the Geological Survey that the estimates of the supply of iron ores which he and the experts of his bureau submitted to the commission were made after the most careful and elaborate study, and that the estimates thus submitted were concurred in by state geologists and mining engineers who were called into conference.

I am further informed by the director that in the estimates which were submitted to the commission, and upon which the commission's report is based, there were taken into consideration all of the ore deposits in the State of Minnesota, and that to be on the safe side—that is to say, not to underestimate—a billion tons more were added to the estimates submitted of the quantity of iron ore in Minnesota than the officials of the State of Minnesota themselves placed upon the same.

The tax commission of the State of Minnesota estimated the iron ore in the Mesabi and other ranges in Minnesota at a billion tons less than the figures submitted to the National Conservation Commission by the federal experts.

So that, with due deference to the governor of Minnesota, whose speech, without intending it, challenged the accuracy of the report of the conservation commission on an important point, I beg to submit that it is more likely the reports of the government officials, men who have been giving close study to this matter for years, and particularly so since the appointment by the President in June last of the National Conservation Commission, are more apt to be correct in the estimates they give than are the reports from other sources whence came the information upon which the governor based his statement.

Now, answering in part the inquiry of Senator Newlands, as to what has been done by the several States since this question of conservation has assumed national proportions, I wish to say that in my own State of Louisiana, by authority of law enacted since the President called the governors in conference in May last, a state commission on conservation has been appointed and is beginning its work of taking an account of the natural resources of the State. In that connection I will repeat to the gentlemen who are here in conference with the National Conservation Commission some things about the resources of Louisiana that I stated to the commission itself during its sessions in the last week.

Strange as it may seem for a State lying as low upon the Gulf of Mexico as does the State of Louisiana, she ranks quite high upon the list of mineral-producing States. We have no coal and iron, none at least that have been discovered as yet; nor have we gold and silver. We have no copper, zinc, or lead. But we have what is now thought to be by scientists the most remarkable supply of natural gas yet discovered.

In the Caddo field, in northwest Louisiana, there are gas wells that are attracting the attention of the world. Some of these wells have been burning for three and a half years. A German expert who came over to this country recently, charged with the duty of looking into the natural gas and fuel oil conditions in the United States, visited the Caddo field in Louisiana and reported that there were being wasted there by "wild" wells as much as 70,000,000 cubic feet of natural gas a day—enough to supply each day the needs of ten cities the size of Washington.

Then we have in the same field, perhaps, as great, if not a greater, deposit of fuel oil than has yet been discovered in the United States.

There are individual wells in the Jennings field, in southwest Louisiana, that have a record of having produced more than 3,000,000 barrels of oil each, and are still producing. I have been told by geologists that there are no wells elsewhere in the United States with any such record of production as that.

Since I made that statement to the National Conservation Commission, Congressman Broussard, of Louisiana, whose district includes the Jennings field, tells me that I underestimated the production of some of the wells in that field.

Then, we have in Louisiana the greatest sulphur mine ever discovered in any country in any age. It is a fact that Louisiana sulphur to-day is supplying the needs of the world for sulphur. We are underselling in the markets of Europe—even in Italy—the Sicilian production of sulphur.

And then, in the matter of rock salt, 99 per cent pure, there are deposits in Louisiana through which the drill goes for 2,200 feet without touching the bottom. This salt is found over a large area of the low-lying lands upon the Gulf of Mexico within the limits of the State of Louisiana.

And then, gentlemen of the conference, in the matter of lumber production Louisiana is next to the State of Washington. Our forests of longleaf pine and of shortleaf pine are very extensive. Cotton, corn, sugar cane, and rice grow on our rich lands in equal luxuriance in the same 50-acre field.

So that it is a State just now realizing what it has in the way of bounties bestowed by nature. Public sentiment is being aroused there, and it is not necessary to say to gentlemen of the intelligence of those before me that if we are to carry through this great policy of conservation of the natural resources of the country the first and foremost thing to do is to educate the people as to the facts of the wastefulness of the supply now going on and of the duty of this generation and coming generations to preserve these resources and hand them on down unimpaired to future generations, for it is only by such education that a popular sentiment so necessary to put behind this movement can be developed.

Forestry—how to preserve our forests—is attracting much attention in the Southern States. But very little is known of the subject, and the practice of forestry is next to nothing. Information, facts, lectures, education along these lines are needed. If only the legislatures of the States, when they meet, would extend invitations to the Forest Service of the United States Government to send men skilled in this service to talk to them, to appear before committees, much might be accomplished in pointing the way to useful legislation.

The average legislator has not had the opportunity to know about these things. He has been busy with other matters. He is too busy to read the pamphlets on forestry sent him. He goes to the capital with the idea that something ought to be done, but with no practical plan for the doing of that something. He needs to be told; to have the way pointed out to him.

Of course, the federal authorities would not think of going into a State, or into the capital of a State, when the legislature is in session, in connection with the matter I suggest, without an invitation. They are careful always to avoid the criticism of interference on the part of the Federal Government with state affairs. But if the governors or the legislatures of States, desiring knowledge about this, wanting lectures delivered giving facts and figures, would suggest the coming of experts or trained men, I do not doubt that the several departments or bureaus of the Federal Government would be willing to respond by sending men who would appear before the appropriate committees and give the practical instruction so essential to the making of progress in forestry.

The report of the National Conservation Commission and the papers forming the appendix thereto should be read by every intelligent man and woman in the land. But how many will read them, or get the chance to read them? Literature of that kind is difficult to get out among the masses of the people. Even when sent out, how many of those into whose hands they come read them?

But if the legislature be in session, and a man who knows the facts and figures and can talk them appears, he will be listened to. All that is necessary to develop the public opinion, so necessary, is for the facts to be disseminated generally among the people.

MR. J. N. TEAL, CHAIRMAN OF OREGON STATE CONSERVATION COMMISSION.

Mr. TEAL. Mr. Chairman, I will make a very brief report. While you all doubtless would be very glad to hear about the resources of Oregon, and I would be delighted to tell you about them if I had time, the hour is getting late and I do not consider that to be the particular purpose of this meeting.

The governor of our State appointed a commission, of which I had the honor to be elected chairman. That commission has prepared a report, printed it, and filed it with the National Commission. There are some of these reports here, and if any of you gentlemen desire copies or have any interest in the method by which we looked into this subject, I shall be delighted to have you take one of the reports, and from a reading of it you will doubtless discover how ignorant we are of the resources of our own State, and, possibly, the reason why I do not care to talk more about them. There is one thing, however, we discovered, which doubtless any commission will discover when it goes into the matter, and that is the enormous and almost wanton waste of our natural resources. Without going into that question, I think it is conceded generally that such is the fact. It is also conceded that this waste must cease. Another question, one of law, which should be conceded (and if not acknowledged sooner or later there is little good of going further) is one upon which we can all work with safety, and that is in dealing with these public resources we are in effect trustees, and we have no more right to dissipate the principal of the fund that has been temporarily placed in our hands than a trustee under a will or a guardian has a right to dissipate the funds of an estate or of children in his charge or control. In my judgment this is fundamental. To illustrate, take a water power, which is certainly a natural resource. To think a legislative body, by its mere ipse dixit, can make it possible for one to acquire a fee-simple title to such a power in perpetuity is shocking. If such is the law as applying to existing rights, then provision should be made to prevent such a condition as to powers which the State and nation still control. I do not mean by this that "powers" any more than other resources should not be used. I would promote a free use, but it should also be a beneficial one. In my opinion the monopoly of water powers should be made impossible. But I am not discussing these questions now. It is easy to talk of generalities and it is easy to pass resolutions based on them. I believe in the conservation of our natural resources. How are we going to conserve them? In my judgment, before this convention adjourns, some practical scheme should be devised, some basis upon which we can all act hereafter. I would recommend that a resolution be offered by some of the governors and adopted covering the following suggestions:

First. That the National Conservation Commission be made a legal body, resting upon the same basis of authority as any other department of the Government, with sufficient funds to enable it to carry on its work properly.

Second. There should be the closest relationship between the States and the General Government. The States, through their governors, should be the connecting link between the National Conservation Commission and the state conservation commissions, and the powers of the State and of the nation should be coordinated and work together.

If we do that, and follow it up by action, we will have taken an important forward step and will have the consciousness of having made an honest effort to pass down to the future, unimpaired, the trust which has been placed in our hands, and preserve for the future our great natural resources, which should and can be made a source of comfort, wealth, and happiness forever.

PROF. G. E. CONDRA, CHAIRMAN NEBRASKA STATE CONSERVATION COMMISSION.

Professor Condra. Mr. Chairman and members of the commission, I will speak briefly for Nebraska as Governor Sheldon's representative.

It has been my privilege and duty during the past fifteen years to study the geography and economic geology of our State. This experience has caused me to reach certain conclusions pertaining to Nebraska's resources and possibilities. Let me refer briefly to some of the Nebraska conditions, because reference has been made to the same by preceding speakers. Our State is large, diverse, and as a rule, rich. It has large areas of both fertile and poor land. Forty thousand square miles of an agricultural region in the east and south countries, being eight times the area of Connecticut, are well developed, with its land ranging from $75 to $150 per acre in value. The day of homesteading has long since passed in this part of the State. Now, its landscape presents a continuous view of alfalfa, wheat, corn, and modern farm buildings.

Lying to the north and west of our most prosperous agricultural area are about 20,000 square miles of sand-hill country, covered for the most part with a thin stand of native grasses. I know that 640 acres of the average of this will not support an American family. If this statement is correct, then the Senator who wishes to restrict homestead to 320 acres in this locality is probably wrong. The soil contains little humus; it is not strong. There is a lack of the necessary elements and conditions for the successful growth of the common crops. Grazing is the leading industry, and for this purpose the region is moderately well occupied, most of the hay flats being deeded land.

The western part of our State, occupying more than 12,000 square miles of the high plains region, is good and bad. It is a place where the influences of rainfall, structure, soil texture, and irrigation water are most marked, and the home of the various forms of reclamation. I can take you to certain localities in this region where good crops of wheat, oats, alfalfa, and potatoes are produced under a low rainfall without irrigation. It is where the soil is close textured and deep. Popularly such cultivation is known as dry farming. Near these fertile places occur sandy soils, underlain by bedrock near the surface, on which crops do not withstand drouth. Some of this land is better adapted to grazing than to any other purpose. Notwithstanding this fact, the native sod on many acres of this strictly grazing land has been turned by would-be farmers. In marked contrast to these high, dry, sandy lands are the many thousands of acres now in successful irrigation, especially along the North Platte.

Gentlemen, it appears to me that our first duty along the line of the conservation of land resources in Nebraska is to obtain a deep insight into the agricultural conditions and possibilities of each of our four soil regions, and that our second duty, sometimes an unpleasant one, is to tell the exact truth of these conditions and possibilities, so that homesteaders and homeseekers, mostly from the East, may come knowingly into their new environs and adapt themselves accordingly. Grave misfortunes result from the settlement of an unfavorable region by an agricultural people. Too many citizens now leave their fertile fields and happy homes, through ignorance and misrepresentation, and find their way to places where the possibilities of disappointment and failure are altogether too great. It appears to me that the Federal Government should investigate and make known both the favorable and the unfavorable conditions that obtain on public domain preceding settlement. And I believe also that each State, in cooperation with the Federal Government, should investigate and publish for the free use of its citizens, something concerning the nature, efficiency, possibilities, and impossibilities of each class of land now occupied, so that farmers may have a proper basis for farm management, leading to the conservation of soil fertility, a thing which is necessary for the future of our agricultural industries.

Having spoken plainly concerning these matters, you will please permit me to say a word on a subject which was discussed at length by the gentleman from Minnesota. It is in regard to the supposed increase in rainfall and the westward movement of the rain belt. This subject comes close home to persons living in western Nebraska. Four times, during periods of heavy rainfall, coming at intervals of eight and twelve years, have the people of Nebraska and adjacent States moved onto high, dry lands, believing in the fallacy of an increasing rainfall. The experiment has proved a costly one, resulting in the establishment of a permanent agriculture only in the most favored places. The facts are, that there is fluctuation in rainfall, but no permanent increase. It returns to about the same mean, if we average the wet and dry periods. However, we have learned that the amount of rainfall is not a complete check or control of agricultural development. The climate of the soil, not of the air, is more important. This varies with soil type, is related to the quantity of rainfall, and affected by cultivation and the kind of crop. This changed climate of the soil, resulting from cultivation and other conditions, is probably what most people mistake for an increasing rainfall.

Now, the matter of fluctuations of rainfall prevails throughout most, if not all, of the United States, but the effects therefrom are most marked in the drier regions, as in parts of Nebraska, Kansas, Wyoming, Colorado, New Mexico, Oklahoma, and Texas. The phenomenon has a close relation to farm management and to the agricultural practicum on the least drouth-resistant soils of these States. Let us meet the problems of soil conditions and of climate, as such, with a farm management that is suited to the nature of these conditions, for these and other related factors must be reckoned with in the establishment of permanent industry in that part of the country.

As regards conservation work in Nebraska, I wish to state that our governor has decided to appoint a commission to be composed of scientific men actively engaged in a study of the State's natural resources. Most of these men head departments in the State university. They are free from politics and in a position to stand strongly for any policy that may seem best for the permanent good of the State. We propose to work along the line of our leading interests, which are largely agricultural. One of our largest problems appears to be the conservation of soil fertility of the rich farm lands. We expect to investigate soil erosion and to advocate crop rotation. Among our other problems are those of the proper management and utilization of flood lands, steep slope lands, sand-hill areas, bad lands, and the high plains areas. Our farmers begin to realize that they should give more attention to the natural and the proper distribution of forest, grass land, and the cultivated crops if the land resources are to be conserved.

Nebraska is large enough and rich enough in her agricultural resources to stand on her own bill of facts, without any attempt to overdraw her possibilities. Her citizens believe in research. They understand the importance of cooperation and the economic utilization of our national resources, both State and national. To this end they join heartily in the great movement in which we are engaged.

DR. J. T. ROTHROCK, CHAIRMAN OF PENNSYLVANIA STATE CONSERVATION COMMISSION.

Doctor **Rothrock**. I wish to say that the governor of Pennsylvania has responded to your call for the appointment of a conservation commission. There are five of us here ready to cooperate with you in any way that seems possible. But I wish to say, first of all, that this conservation business is not a new thing in Pennsylvania. For more than twenty years the State of Pennsylvania has been on the firing line.

Twenty years ago a forestry association was organized in the State of Pennsylvania. To-day, as a result of that forestry association, we have nearly 1,000,000 acres of land purchased from the citizens of the State and turned over to the State as a forest reservation.

I wish to say the people of Pennsylvania are so thoroughly in earnest about this matter that they have paid more to get that land back in a stripped condition than the State received for it when it was sold with heavy timber on it.

We are in earnest up there. We believe in this conservation work.

I wish to say, furthermore, that we are taking in young men from over the State to make foresters of them. We do not know what their politics may be; we do not care what their politics are. We put those young men through a preliminary examination, first, physically, to see whether they are able to stand the duties of the forest service, then a mental examination, and then at the expense of the State of Pennsylvania we educate them, just as young men are educated at Annapolis and West Point. They are to be the servants of the State. Three years after their graduation they give their time to the service of the Commonwealth. We are in earnest about the education of our corps of foresters who are to care for this state land.

We furthermore recognize that you can not get a people to take up the abstract idea at present of forestry as a thing which is desirable. A great many people do not understand it. A great many do not want to understand it. But we invite the public out into our lands.

There is no prohibition there to keep off of the grass; to keep out of the grounds. We invite them in. You can not get people interested in land, even land that belongs to them through the State, unless they are taken out into it.

We have opened upon our reservation a sanitarium, and this year $1,000,000 has been invested by the State of Pennsylvania for the erection of a sanitarium for tuberculosis on state ground, ground that belongs to the people of Pennsylvania.

These are just some of the things we are doing there. We have published a little journal in the State of Pennsylvania for over twenty years now. It goes broadcast over the State, and, we may say, almost without subscriptions. It is practically freely distributed.

Mr. President, I do not want to take your time. I simply call your attention to the fact that the State of Pennsylvania is already in line. All its preliminary work is done. Our decks are cleared for action, Mr. President, and we simply await the order to go ahead.

Senator SMOOT. I would like to call the attention of the convention to the fact that it is now five minutes to 5 o'clock, and there are a great many here who may have made arrangements for other meetings, and I would therefore like to move that we now adjourn until to-morrow morning.

The CHAIRMAN. Two or three have been recognized and we might hear from those first. At any rate, I shall ask your indulgence to make an announcement or two before adjournment is taken.

Senator SMOOT. I will withdraw my motion to adjourn, then, for the time being.

The CHAIRMAN. I wish to make two announcements. The request was that the committee consisting of the present governors and the past governors and the governors-elect meet here immediately at the conclusion of this session.

The committee on presentation of the waterway matter to the Senate Committee on Commerce will be appointed to-morrow morning. In the meantime I ask all state delegations to give me the names of their representatives.

I heard from Judge Richards, this afternoon, the only valid reason that has been given in the last two days—the only good reasons—why anybody should have a good opinion of me. I have had far more credit, gentlemen, than ever belonged to any one man, and most of what has been said about me really should have been said about men who have been doing more good work along this line than I have—Doctor McGee, Mr. Price, Doctor Holmes, and Mr. Woodruff, Mr. Shipp, and a lot of others.

They are the men that ought to have had the credit, and not me. Now, it is needless to say that I court your good opinion.

I see but one way that offers a fairly certain route for me to get it; that is, I want you all to meet my mother, and it would give my mother and me very great pleasure if the members of the conference would do us the honor to come to our house to-morrow night at 9 o'clock for a thoroughly informal reception. It is not a dress occasion. I want you to come up there and give her the pleasure of meeting you, and I think I may fairly say, give you the pleasure of meeting her.

I now recur to Senator Smoot's motion. It has been moved and seconded that this conference now adjourn until 10 o'clock to-morrow morning.

(The question was taken and the motion was agreed to.)

(Accordingly, at 5 o'clock p. m., the conference adjourned until Thursday, December 10, at 10 o'clock a. m.)

THURSDAY MORNING, DECEMBER 10.

The conference was called to order at 10 o'clock a. m. by the chairman, Mr. Pinchot.

The CHAIRMAN. Gentlemen, before we proceed with the consideration of the subject of forests, which Senator Smoot, chairman of the section of forests of the National Conservation Commission, is to present, I have to announce the appointment of a committee of this conference to attend the meeting of the Senate Committee on Commerce to-morrow morning at half-past 10 o'clock at the Capitol. I shall ask Governor Deneen, of Illinois, Governor Johnson, of Minnesota, and Mr. William K. Kavanaugh to form the special committee of three which I was directed to appoint. I have received nominations for the general committee from the following States: Rhode Island, New Jersey, Alabama, Colorado, Tennessee, Kentucky, Georgia, Wyoming, Indiana, Pennsylvania, New York, West Virginia, Missouri, Utah, Virginia, Mississippi, California, and Michigan, with other state delegations yet to hear from.

There is a great deal of business to come before us to-day, and I venture the suggestion to the conference, which will do with it as it may please, that you instruct your chairman to limit the speakers to ten minutes. If you do this, I shall take the liberty of disregarding your instructions in the matter of the governors who may address us, but I shall strictly keep everybody else within the limit.

(Upon motion, the suggestion of the chairman was adopted.)

SENATOR REED SMOOT, CHAIRMAN OF THE SECTION OF FORESTS, NATIONAL CONSERVATION COMMISSION.

The CHAIRMAN. I have now the very great pleasure of presenting to you Senator Smoot, of Utah, chairman of the section of forests, who will present that part of the commission's report to you for your consideration.

Senator SMOOT. Mr. Chairman, governors, and members of the state and national conservation commissions: I take it that we are here this morning for the purpose of considering seriously the vital questions affecting the conservation and the proper utilization of the forests of our country. It is a subject greater than any man, greater than any State; it is as great as the nation itself. Every man, woman, and child of to-day, and every one yet to be born, is interested in this great question. You no doubt have noticed that in all the previous discussions of this conference the question of the conservation and the use of the forests has played an important part. In my remarks I do not intend to call special attention to any of the great resources of any particular State, because there is not a single governor here or state representative who could not sing the praises of his own State and speak of the wonders of its natural resources. I wish to present to you and emphasize, if possible, some of the points that have been made in the report of the National Conservation Commission, which report I hope will be approved by this conference and then submitted to the President of the United States.

God has blessed this beautiful land of liberty most lavishly and richly; no country on earth has been given so many natural resources, and it seems to me that in the past we have been lax, indeed, in trying to preserve them not only for ourselves but for future posterity.

Gentlemen, yesterday you heard the report of the committee wherein it was stated that an inventory of our forest resources had just been completed, which is the best we have ever possessed. This inventory is the result of the combined and vigorous effort of all state and federal agencies concerned.

The facts which flow from this great accumulation of knowledge regarding our forests will soon be made common knowledge, as they ought to be. From these facts three great conclusions spring; the first, that the forest problem before the individual, the State, and the nation is grave and urgent; the second, that we can solve this problem if we act unitedly, vigorously, and at once; the third, that if we fail to act, the possibility of a satisfactory solution will be rendered doubtful or even wholly removed. The time is past for us to be content to dabble with the vital internal question which the right handling of our forests presents. It may well be our pride that no nation has a more wholesome and enthusiastic public sentiment for the right use of the forests than our own, but it may well be our shame that no nation takes poorer care of its private forests than our own country.

This is not the time for harsh criticism of the agencies which have brought about the deplorable condition of our forests. But above all it is the time for prompt, effective, and united effort to remedy this condition. The time has long past when the only need for the conservation of our forests was in order that we might fulfill our duty to those who come after us. The time is already here when for our immediate welfare the conservation of all forests in private as well as in public lands is absolutely essential. Forestry no longer makes its appeal to the American people solely through their sense of public duty. Its appeal now rests upon a firm foundation, not only of public duty, but of urgent industrial and commercial necessity.

I wish at this time to call your attention to some of the special items of that report again, so that you may each be impressed with the importance of this particular fact.

Consider the situation. This nation began with half its area under forest. To-day barely one-fourth of our country is covered by forest growth. Only one-fifth of the standing timber which remains is in public ownership, and therefore belongs to the people. Four-fifths of what remains is in private hands. Year by year we take more and more wood from our forests, and year by year by careless cutting and by fire we lower their capacity to produce again. The yearly production of our forests by growth is 7,000,000,000 cubic feet, a volume of timber so great that the mind can scarce comprehend it; but a volume of timber over three times as large is taken from our forests each year. Nor is this the complete indictment against us as a nation for our misuse of the forest. We invite by overtaxation the destructive handling of forest lands. We should plant, to protect farms from wind and to make stripped or treeless lands productive, an area larger than Pennsylvania, Ohio, and West Virginia combined. But so far lands successfully planted to trees make a total area smaller than Rhode Island.

It seems to me one of the most destructive elements of our forests comes from forest fires, and if the governors can in any way educate the individual who owns the forest upon this point of view, this meeting will not have failed. I was visiting the Appalachian country a short time ago and had the pleasure of inspecting the great Biltmore estate. One of the party asked Dr. C. A. Schenck, the forester in charge, if he had $5,000,000, the interest on which was to be used by him for the preservation of forests, what he would do with it. His answer was without hesitation, "I would use every dollar of it for a fire patrol." Asked again if he had the interest on $20,000,000 what he would do with that, he replied, "I would increase my fire patrol just four times."

Since 1870 forest fires have each year destroyed an average of 50 lives and $50,000,000 worth of timber. Not less than 50,000,000 acres of forest is burned over yearly.

One-fourth of the standing timber is left, or otherwise lost in logging. The boxing of the long-leaf pine for turpentine has destroyed one-fifth of the forests worked. The loss in the mill is from one-third to two-thirds of the timber sawed; the loss in the mill product, through seasoning and fitting for use, is from one-seventh to one-fourth. The damage done by destructive forest insects is enormous and largely preventable. Only 320 feet of lumber are used to each 1,000 feet which stood in the forest.

Nor is the indictment yet complete. By the needless destruction of our forests we impair the value of our streams for navigation, irrigation, water supply, and power. We spend millions of dollars in river and harbor improvements to repair damage which, at the cost of mere thrift and foresight could have been nearly all avoided. We deal with the effects and ignore the cause. We discuss the exact scientific relation between the forest and the stream, when each year the total quantity of silt carried by our rivers as the result of forest denudation and poor soil management would cover 1 foot deep a surface of more than 900 square miles. In our blindness we have failed to take advantage of the lessons which the history of other nations contains. Most other countries have learned through bitter experience that forests which are not conserved will be used up, and they are taking care of what they have. We are among the last to learn it.

So much for the indictment. Every clause in it is absolutely true. What would you think of the business capacity and the foresight of an individual against whom such an indictment might justly be read? So much for where we stand. Now let us consider what must be done, and where we might stand if it were done.

These are the things which we must do; they involve no intricate machinery of law or practice; they are simply incontrovertible conclusions based upon the conditions which now exist and which must be remedied: First in importance is the conserving of forests in private lands. Private forest owners, which means 3,000,000 men, and individual forest users, which means everyone, must practice reasonable economy in the woods in logging, in milling, and in the use of timber. Above all they must protect their forests from fire. This they can do at an annual cost equal to one-fifth of the damage forest fires do each year, not counting injury to young growth. And it is this young growth which, if preserved, would grow a constant supply of timber for those who come after us. I do not ask of the private owner and user that he apply any economy which is not entirely practicable, and which does not mean present as well as permanent profit. I ask only that he protect his forest from fire, that he log it conservatively, and that he plant uplands suited only to forest which have been so denuded of trees that they now fail even to pay the taxes levied upon them. To justify private owners in applying those measures, two main conditions are necessary, both of which exist to-day: The one, a knowledge of the central fact that these measures are needed and that they will pay; the other, the availability of knowledge as to how these measures may best be applied. If anything I could say to the governors to-day that seems more important than another, it would be to return home to your States and educate the people.

One of the urgent tasks before the States is the immediate passage of tax laws which will enable the private owner to protect and keep productive under forest those lands suitable only for forest growth. In our discussion in committee meeting there was a question raised by a member present as to this recommendation, claiming that it would encourage great monopolies in securing larger holdings of timber, if an annual tax was not required on the timber itself. I have studied this question in foreign lands, particularly in Germany and Switzerland, and I find that the result has been exactly the opposite. It does seem to me that the great monopolies that control vast tracts of our timber land can much better afford to pay an annual tax on their timber than can the individual man with scanty means at his command who believes in reforestation and upon whom such a tax would be a burden so great that it would be almost impossible for him to carry it. I believe, with all my soul, in the tax laws as recommended in our report. It is a shortsighted policy which invites, through excessive taxation, the destruction of the only crop which steep mountain lands will produce profitably. Taxes on forest land should be levied on the crop when cut, not on the basis of a general property tax—that unsound method of taxation long abandoned by every other great nation.

Another urgent task before every great forest State is not only the passage of adequate fire laws, but their actual enforcement. More is needed to protect the forest from fire than a law upon the statute books. It requires the definite commitment of all the States to their inherent responsibility for the protection of the forests within their boundaries from fire, and that entails, and absolutely entails, the employment of a trained force whose first duty is fire patrol. A few days ago I heard a very prominent gentleman from West Virginia testify before the National Conservation Commission that the forest fires of West Virginia alone this year have cost that State, in the loss of timber, $5,000,000. A fire patrol that would cost the State of West Virgina $100,000 would be ample to protect that State against forest fires. Think of it, gentlemen, the loss in this one year in the State of West Virginia was sufficient to patrol that State for its protection against forest fires for fifty long years.

The nation, through the Federal Government, confronts the urgent duty of conserving all, not merely a part, of the public forest lands by use. Until this standing timber is adequately protected and conservatively used, not only as at present on national forests, but on all other public forest lands as well, its very existence is imperiled. Grave injury has already been done. It would be a national disgrace should it continue.

I have recently visited that great and beautiful forest region which lies within the southern Appalachian Mountains, and I have this to say regarding the proposed purchase of a small portion of it by the Federal Government for the permanent use of the whole people. I believe as firmly as I believe that I am standing here on this platform that unless adequate action is taken, and taken soon, the destruction now going rapidly on in the Appalachian Mountains will either become irretrievable, or retrievable only at an expense so vast in time and money that it would stagger this nation. I do not believe that it is necessary or advisable for the Federal Government to acquire all mountain forests in this region, nor half of them, nor a fourth of them. The purchase of one-twentieth of these mountain forest lands, their protection from fire, and their conservation by use, would solve, and solve satisfactorily, this grave and urgent problem. But this entails, as every other effective national measure for the preservation of the forest entails, for its success, the cooperation of the State concerned, through fire protection, and of the private forest owners concerned, through better handling of forest lands in private ownership.

These are the incontrovertible conclusions which flow from the knowledge of how we stand along main lines with relation to the forest. Unless we do these things our forests will inevitably fail, and the failure of our forests means the erosion of soil upon the mountains and a falling off in the usefulness of our streams. Action upon each of these conclusions requires no vast expenditures, no upheaval in present economic conditions, but merely the exercise of reasonable foresight and thrift by individual forest owners and users, by all the States, and by the nation. No one of these great agencies can alone solve our forest problem. They must work together, unitedly, vigorously, adequately, and at once. If they act together and now, we need not worry greatly about our future timber supply. If they fail to act, it will mean inevitable and grave timber scarcity in the near future and actual timber famine for those who come after us.

We can no more disregard in our use of the forest than in our use of the mine, of the stream, and of the farm the fundamental truth that want follows close upon the heels of waste. But we should be thankful as individual forest owners and forest users, thankful as individual States, and thankful as a federation of States that the time for the application of an adequate remedy is not wholly past. Grave injury has been done to our country, which can not be repaired in a year, nor a decade, nor wholly effaced in a century; but the fact gained by our present inventory, above all other facts in importance, is, that if we act at once we still have forest enough left to produce, under right management, at least what timber we need.

The cause of practical forestry is a just cause. On the one side are established habits of wastefulness and of misuse; on the other side is the doctrine of common sense, of business sagacity, of public duty. Because I believe in the American people, I believe that they will follow the right course and turn away from the wrong in this, as in all other crucial questions upon which depends the permanent welfare of our country.

MR. ROSEWELL PAGE, OF VIRGINIA.

The CHAIRMAN. I will now call upon Mr. Page, of Virginia, for a statement of Virginia's views upon the questions we are considering to-day.

Mr. PAGE. Mr. Chairman and gentlemen, members of this conference, I want to say, as the representative of the governor of Virginia, how sorry he is not to be present at this great conference; but certain engagements, which had been made previously, prevented his being here, and he has done me the honor to send me here to represent him. I desire to say, as a representative of old Virginia, that on yesterday I was a little aggrieved at the tone which was exhibited by the governor of the great State at the mouth of the Mississippi towards the statement made by the governor of the great State at the head of the Mississippi. I felt as if I had a right, coming from old Virginia, which has had such an interest in those two great States, a historical fact to which I need not further refer in this presence, to say, "Remember that ye be brethren." I felt, furthermore, that I would like to say in behalf of this great conference that it would probably be apt if we could understand that each in speaking of his State is a little inclined to be as an old friend of mine said about another friend of mine, "a little paradeful." Therefore I thought it would be just to say to the distinguished governor of Louisiana that I think he was almost as exuberant with reference to that salt and that sulphur of his State as was the governor of Minnesota with reference to the iron in the Mesabi Range.

I am informed of the fact that to-day the subject is that of forests, while on yesterday the whole range of sky and earth and under the earth was taken when the subject was lands. I think to-day, inasmuch as we only have ten minutes—at least those who are not governors—perhaps we will have to stick to our text. You will remember the old story. Down in Virginia—I have told this story before—an old colored man was asked if he were a preacher. He said "No, I am a 'zorter." Being asked what he meant by an "exhorter," he replied: "If you are a preacher, you have to stick to your text, but if you are a 'zorter, you can branch."

The governor of Virginia has already appointed a distinguished commission. I shall not undertake to give to you the result of the work of that commission, but it will be furnished to the chairman of this conference in order that it may have a fit place among the records of this meeting.[a]

I can simply say this, that I am perhaps one of the few delegates to this conference who really, from necessity, should be an expert on forests, because I live in the woods. I consider it a great fortune to be able to-day to do that, and I also can say to you that there is great need of the preservation of the forests. I have known it to be the case that an acre of fine walnut timber has been cut down in the mountains of Virginia to enable them to sow buckwheat, and I am reminded of the fact of a distinguished friend of mine who, after forty years, took his wife on a bridal trip and they came to one of the great cities. A young furniture dealer was showing them his stock of furniture, in the hope of making a sale. He said, "This is solid walnut, and that is solid walnut, and this is solid walnut," and the old gentleman did not seem to be very much impressed by it. The furniture man seemed somewhat surprised, but was overwhelmed when the visitor said: "Look here, young man, by God, I come from a country where folks make fence rails out of walnut."

You can not make fence rails out of walnut now, but I have knowledge of a telephone line where some of the telephone poles are made of black walnut. Some day some man will come along and buy up that telephone line, but he will not do it because of the money he will make off of the wires, but because of the value of those poles.

I have simply risen to tell you that the governor of Virginia has appointed a State conservation commission and to say that he bids me express to you the fact that this conference can rely upon him to do whatever is within the power of the State—and I think there is great power in the State. As a member of the general assembly of Virginia, I think there is great power in the State for good along the lines for which our distinguished chairman has so well, to use a forestry term, blazed the way.

MR. WILLIAM E. MULLEN, OF WYOMING.

The CHAIRMAN. I take pleasure now, gentlemen, in introducing to you a representative of the governor of Wyoming, Mr. Mullen.

Mr. MULLEN. Mr. Chairman, ladies, and gentlemen, I appear at this meeting as one of the younger States, or rather as a representative of the governor of one of the younger States. I do not know whether our governor was one of those who, having attended the White House meeting last May, concluded that it would not be a desirable place for future residence. At any rate, he has asked me to appear here and represent him as best I can.

---

[a] Page 264.

The more I hear of this question of conservation the more deeply I am impressed with the magnitude of the question. Therefore, I do not believe that it would be profitable for me to indulge in a discussion of the local question as applied to our State. Better perhaps to discuss the question in its larger aspects. But there is a thought that I desire to bring before you now, and that is the application of a national policy of conservation in its relation to the settlement and development of the newer States. We have heard a great deal about the older States. Some of them have been held up before us as horrible examples of waste and destruction of natural resources. We of the new States, with undeveloped resources, indulge in the hope that we have a brilliant future before us, and are not in the position of the man described by one of our humorists as a person having a brilliant future behind him. It is perhaps to the advantage of the new States that the idea of conservation has been suggested before they have fallen into the errors of some of the older States in the waste and destruction of nature's bounty.

If you will bear with me for a moment, I will call your attention to a map. This is a map of our State. The green space indicates forest reserves territory; the blue space represents coal lands classified and withdrawn; the yellow represents Indian reservations; the upper corner here represents the Yellowstone National Park; the space in red along the streams represents land withdrawn for purposes of reclamation under government irrigation works.

In the first place we who now reside out there do not assert a claim to all of the unoccupied territory in Wyoming. We have in the State approximately 125,000 people at this time. We have a vast public domain that belongs to the people. It belongs to all of the people of the United States, and we hope that many of them will come to reside in our State in the near future. What I have to say, therefore, refers to the conservation question in such a way that I hope it will appeal to all of you.

The most important thing to insure the success of the conservation movement is, in my judgment, that of state cooperation in the classification of natural resources. I say that for the reason that I have been reliably informed that at least 75 per cent of the territory indicated on this map in blue as coal lands have been classified tentatively by a hurried examination of the surface made by the Geological Survey. It is the opinion of practical mining men that fully that percentage is of no practical value for coal-mining purposes. The opinion may be erroneous, but it is as likely to be correct as any of the conclusions arrived at by a mere examination of the surface. It is not actually known what per cent of this area is valuable for coal-mining purposes, and it will not be known until the lands have been explored by prospecting beneath the surface. And while there may be uncertainty as to the value of these lands for grazing and agricultural purposes under what is known as, in the West, dry-farming methods, and which may be carried on wherever the mean annual rainfall equals 16 inches, many persons have filed claims and settled in this region. Therefore I would suggest, in connection with this question, the great advantage of having local people, who are familiar with the conditions there, who understand soil conditions, and know something of the value of coal deposits commercially, to assist in the classification of coal lands, to the end that the greatest good for the greatest number may be accomplished, as I understand that to be the ultimate aim of the conservation idea.

There is no reason why this great territory should be withheld for coal mining if it be in fact more valuable for purposes of home making. The same is true to some extent in the case of the forest reservations. About one-ninth of our state territory is within national forest reserves. It is nearly all comprised of mountain lands situated at an altitude of from four to ten thousand feet, and much of it is really not valuable for forest culture for the reason that it contains a growth of lodge-pole pine, willow brush, and grass. Forested areas exist in the upper regions, but forest growth is exceedingly slow in high altitudes for the reason that the growing season is short, and it is said to be a fact that trees grown under such conditions produce a grade of lumber much inferior to that grown in lower altitudes.

Then, as to the real and effective work to be carried on for the preservation of timber, I fully corroborate what has been said by Senator Smoot on the general question of waste by fire. While it is true that a considerable percentage of waste occurs around sawmills and that the breaking of log booms on streams results in much loss where logs pass from control and find their way to the sea, the destruction by forest fires far exceeds any of these, and the loss from forest fires has been appalling. I believe that in our State a careful examination will show that where 1 acre of timber has been depleted by cutting for useful purposes, there have been at least 20 acres swept away and destroyed by fire. Long before the creation of forest reserves at all, vast areas of splendid timber were so destroyed, and it presents a sorry spectacle to witness hundreds of acres covered by dead timber strewn in every direction. Careless campers, travelers, and others, passing through the forests, leave smoldering campfires behind them, which are fanned into flame by the winds, and great forest fires result. Too much emphasis can not be placed upon the necessity of a vigilant fire patrol. More can be accomplished by preventative measures than by organizing to fight fires once started. It is a matter that ought to receive careful consideration.

It is the intention of the governor of our State to urge the passage of a law creating a state conservation commission, with full authority to cooperate with the federal authorities on all questions relating to the conservation, care, and administration of our natural resources. It is our belief that many of the errors which have occurred in our forest administration are the result of misunderstandings and errors of judgment on the part of the ranger, whose duty it is to deal with conditions at first hand.

Therefore, Mr. Chairman, it is a pleasure to give assurance to you of our intention to inaugurate at a very early date a state policy of cooperation which we hope and believe will operate to the mutual advantage of all.

I thank you, gentlemen.

The CHAIRMAN. Gentlemen, I want to emphasize just as strongly as I can what Mr. Mullen has just said about the necessity for cooperation between government organizations, state organizations, and individuals in all matters relating to lands or any other resources, forests, waters, minerals, or anything else. One of the essential things this conference ought to bring out is the absolute necessity of our stopping each playing alone in his own yard and getting together in one yard.

It gives me great pleasure to announce at this time that we have with us a representative of one of our neighboring governments, Senator Edwards, of Canada, whom I now present to you for an address.

SENATOR WILLIAM C. EDWARDS, OF CANADA.

Senator EDWARDS. Mr. Chairman, ladies, and gentlemen, this is the first time I have ever appeared before an audience of the great Republic of the United States, and it gives me great pleasure, I assure you, to do so on a subject which is very near and dear to me, that of the conservation of our natural resources.

I am here at the instance of the government of Canada, a government having the kindliest feelings of regard for everything which means the promotion of the good of the great United States.

Before leaving Canada I asked his excellency, the governor-general, "Have you anything to suggest to me about what I shall say or to which I shall particularly refer?" He said, "No, further than to join with that great and progressive man, Mr. Pinchot, in promoting the object which he has in view in this gathering."

Before I overlook it, in the short time I have to address you, I wish to mention now that I also asked our prime minister if he had anything special to mention. "No," he said; "I think you are full of the subject upon which you are going, but there is just one thing on which it would give me great pleasure, if the congress which is to meet in Washington on the conservation of natural resources would pass a resolution suggesting that the Government make most stringent laws with regard to railways in their prevention of fires, for in my opinion they are great disseminators of forest fires." His reason for making that suggestion is that if it should come authoritatively from this source he would have it in his hand as a lever to enable him to pass a similar law in Canada.

I wish before proceeding to congratulate, in the most hearty terms, your President and your worthy chairman for what they are doing in this respect, in the promotion of the conservation of the resources of your great country. I have heard, during the speeches and presentation of the many addresses here, matters which interested me intensely. I am greatly repaid for coming here, if to have heard nothing at all but the presentation of the first report and inventory of your natural resources, and I would have gone many, many miles to have heard it and many miles to have heard many of the other speeches, particularly the one from the gentleman from Colorado [Mr. Richards].

The question this morning is that of the conservation of your forest resources. Like ourselves in Canada, you have been prodigal with your resources. You have unduly destroyed that great resource, and so have we. A speaker a short time ago said, however, that twenty times as much had been destroyed by forest fires as ever was destroyed by the lumberman's ax. I subscribe to that. That is my opinion. Therefore, the greatest means of preventing that great destruction is the prevention of forest fires.

What is the meaning of preserving our forest resources? Not only the conservation of that very useful product for the people, but also the conservation of our waters for power and the many other purposes to which water may be applied. In Canada we are devoting ourselves to-day to the same objects to which you are devoting yourselves, aided and promoted very largely by our friend the chairman, who occasionally visits us in Canada on this very important subject.

We have heard something of your inventory in other resources, as well as those of lumber. Your country of course is a very large one and your resources in respect of lumber have been greater than ours, but to-day we are supposed still to have 535,000,000 acres of forest lands. Out of this quantity of forest lands, the government has set aside, as forest reserves, 121,000,000 acres. I do not know how that compares with yours, but I will say this: Thanks to forestry, thanks to the initiative which has taken place with regard to the conservation of our resources in that respect, if Canada takes the lessons that it should take from such gatherings as this, and even at this late day awakens to the necessity of conservation and promotion of forestry, Canada, in so far as her own needs are concerned, need never want for a supply of timber. I am not of the opinion that Canada can be a large exporting country for many years to come, but it will be a great thing for Canada if she is able to conserve lumber for her own needs. Let us hope that the great American Republic will do the same thing, and I believe it will do so, if regard is paid to the lessons which are here taught, if the country becomes imbued, as I hope it will, with this great necessity; and if this comes about, I think possibly the United States also need never want for a lumber supply.

In listening to the speeches that have taken place here, two things have very forcibly been impressed upon my mind. I never thought before of the important part water may take in the conservation of your coal supply and in the conservation of our coal supply. Our coal supply and your coal supply may become exhausted. Your iron and our iron may in many years become exhausted—however, we also have a great supply of those two articles—but our water supply, if we preserve the headlands in our forests, never will become exhausted. We are doing exactly what you suggest; we are beginning to impound our headwaters to conserve our water supply. If you do what you can do in that respect, look at the great possibilities that there are of to-day beginning to conserve your coal, which is a disappearing quantity.

Another thing which impressed me was what are we going to do when our iron supply becomes exhausted? I was a little surprised to hear that in the middle of the present century iron, as used to-day, of the quality used to-day, will become exhausted. To my mind there is one article that can be considered in the way of conservation of iron ore to a very great extent, and that is the use of cement. I am a lumberman, and a lumberman on somewhat of a large scale. I do not build one single structure to-day of lumber. Every structure that I build is of concrete and steel—largely of concrete. I built a large mill of concrete this very summer, and built a very large factory establishment also, all of concrete. It sounds strange for a lumberman to advocate anything of the kind, but I am one of these lumbermen who believes strongly in the conservation of our forests.

Just before I part from you there is one thing I desire to say to you. Canada has the advantage—and I am surprised to be in position to tell you so, and you will be surprised to hear it, many of you—Canada has the advantage of having secured a large portion of her lumber supply this year from the United States. I am a lumberman, and it sounds strange to come from me, but I want you to send it on. Keep sending it to us. Our timber will grow in the meantime, and we will profit later on.

Gentlemen, I thank you very much for your attention.

MR. FRANK H. LATHROP, OF ALABAMA.

The CHAIRMAN. I will now recognize Mr. Lathrop, of Alabama, for a short address.

Mr. LATHROP. I am living in Alabama, but was reared in Michigan. My mother was a Canadian, and I can appreciate the remarks of the gentleman who preceded me. I come here, ladies and gentlemen, representing the governor of Alabama in forestry, not in politics, because our politics differ. I do not want to be misunderstood on that question.

On September 23, 1908, in the midst of the presidential campaign, I was notified by the governor of Alabama that I had been appointed one of a committee of five to gather statistics and help compile an inventory of the natural resources of the State of Alabama, in line with and in compliance with a unanimous agreement of a conference of governors of the several States made in Washington, D. C., in May preceding of this year.

After November 3, and as soon as I could get my business matters in line after more than two months of inattention, I became convinced that the subject assigned to me, namely, the timber resources of thirty-five north Alabama counties, would be a Herculean task to form a correct estimate of, in a most crude manner, to say nothing of taking a correct inventory of same, to use the words of our correct and business-like governor, who prides himself on his knowledge of business details as well as the name and residence of every new married couple living on the hills of north Alabama, in whose homes and families his face and name are as familiar at this time as is the family Bible, or more so.

Now as to the inventory, or more commonly called "estimate of timber," to use a lumberman's phrase. I find on consulting the highest authority, such as the editor of the recent Lumber or Timber History of the United States, and some of our largest timber or lumber manufacturers, that the heretofore basis of inventories on this asset of the Commonwealth of Alabama is entirely at fault as to the present status of the case. And to sum up the matter, and at the same time sound the warning that has already been voiced by our national forester, Gifford Pinchot, I am compelled to indorse his statement that our forests are not only being denuded at a rapid rate, but also that I do not find over 10 per cent of the original forest now standing in north Alabama. And while more than three-fourths of the territory above described contains a good growth of wood and timber, much of which is what is termed "immature," trees that would become mature in a period of from ten to twenty-five years, if the present condition of said forests could be conserved and protected from the wholesale cutting and denuding process now in vogue by the owners of said lands and timber rights. Also, said timber in various stages of maturity could be made a continuous source of income and profit if a system of cutting the same could be inaugurated similar to the methods of forestry now being protected in the older countries of Europe and in Germany, namely, the methods of marking and cutting trees only that have attained a certain size, and the caring for the children of trees that are immature and under size and age. It would seem that this plan should appeal not only to the general public but also to the owners, when it is demonstrated that the natural growth of small timber trees is greatly accelerated by the thinning-out process, and at the present time, under favorable conditions, amounts to more than $1 per acre per year on reasonably well-wooded land.

I submit herewith my deductions of the entire acreage of 35 counties in north Alabama and the entire amount of commercial timber acreage. Possibly one-third of said timber of acreage showing wood will be cleared and put in cultivation or pasturage during the next six to ten years. The balance, or one-half the lands in said territory, is unfit for cultivation, and can be treated by forestry methods if the denuding methods now going on at a rapid rate should be changed to a more reasonable system of cutting with a view to preserving the future forest area of the State, and the maintaining of a constant and maximum amount of matured annual growth of timber that will command the highest values in lumber and by-products, such as wood for fuel and farm purposes taken from the timber cut and utilized to its fullest extent.

I have submitted to the chairman certain estimates made after my twenty years of observation and operations in manufacturing the timber of north Alabama, which are, in my judgment, not underestimated as to the amount of standing timber that, in its entirety on all the territory, will make lumber of all the forty or more grades and sizes, while the manipulations of grades and sizes of lumber can be added to by using the small trees. As a rule, the matter of cutting small trees is simply a matter of turning a day's value of work into a dollar without profit, hence is termed in lumber terms, "simply a bread and no butter business." That should be a strong appeal to a more liberal and philanthropic method of treating one of the main, if not the main, assets for conservation, of one of the main resources of the State, keeping ever in mind the great fact that the life of the State and nation depends absolutely on our material resources and the conservation of said resources.

MR. ANDREW CARNEGIE.

The CHAIRMAN. Among our distinguished guests to-day is one whom we all know, and from whom we shall be glad to hear. I refer to Mr. Andrew Carnegie, whom I now take pleasure in introducing to you.

Mr. CARNEGIE. Mr. Chairman and gentlemen, circumstances over which I had no control have prevented me from being with you before. I want to tell you how enthused, how elevated, how delighted, how instructed I have been by this meeting. I have not enjoyed a morning like this at a meeting for a long time, and I will tell you why.

The great obstacle to the reforms for which we work to-day, the conservation of our resources, lies in a federal system of government, the General Government. None of us would part with that. The relation of the Federal Government to that of the States is a matter of decided importance, of course. That relation should continue. We must have it. The great obstacle to-day, as you see, is to get the States and the nation to work together. That is the one obstacle we must overcome. I told the waterways commission a story to show how rapidly we are advancing and sinking—not obliterating the State into the nation. We are all members of one or other of the States, Pennsylvania, Alabama, South Carolina, Virginia, Minnesota, or another. But we are something higher and wider. We are all Americans! Let us remember that.

I asked Mr. Blaine once, "What is the most effective speech you ever heard in Congress?" "I will tell you," he said. "It was the first time that it was proposed to appropriate national money for fresh-water improvements, and the House became excited and angry. Governor Ritter, of Pennsylvania, had been elected a Member of Congress. He had never spoken before, but to the astonishment of the Speaker the old gentleman arose. The House hushed in a moment. Every one wondered "What is coming?" Governor Ritter said:

> Mr. Speaker, I do not know nothin particulars about the Constitution, but I know this: I would not give a cent for a Constitution that would not wash just as well in fresh water as it did in salt water.

The House did what you did, gentlemen. It burst into one storm of applause, and that bill was passed, and that is the foundation of our whole fresh-water improvement today. Go on in that direction. Let us go further and further and all will be well.

I wish to say something to the gentleman from Canada. I am a broad American. No lines confine me in that respect. The city of Winnipeg has a library I gave. They founded a historical society, and the first honorary member was your humble servant. I wrote them telling how delighted I was, first, because they were Scotch, and, second, they were our great neighbors; and they were going to record their history as they made it—they were up to date. Then I said that I always felt that Canada occupied with reference to the United States the proud position that Scotland occupied with regard to her southern neighbor, England. Scotland, through its King, annexed England and has ruled it ever since for England's good.

Now, that is the destiny that I predict for North America. Canada will play the part of Scotland; she will annex her southern neighbor and do it incalculable good in giving us more of the strain of that invaluable element which has made North Carolina and South Carolina and not a few other lands so great, the Scotch.

Gentlemen, that is all I wish to say to you, but remember one thing—and it is an audience like this that should hear it—you are loyal people of your States, but thank God for this, that even above your love for your State you have the greatest empire that ever the sun shone upon and you are progressing splendidly, marching forward rapidly. You people here, you ardent reformers, and you, my dear friend, Mr. Pinchot, think we are not marching fast enough. We are driving pretty fast, gentlemen; we are driving well, and there is no limit to what this great continent is to be in the future. Good morning.

The CHAIRMAN. I have one other request to make of the gentlemen who have asked for recognition. I see that Governor Pardee, of California, has come in, and I know as governor he ought to have the right of way, even though he is not the actual governor for the moment. I am sure we shall be glad to hear him.

EX-GOVERNOR GEORGE C. PARDEE, OF CALIFORNIA.

Mr. Chairman and gentlemen, I hope you will all agree with me when I say that three Presidents of the United States stand out head and shoulders above their great fellows: Washington, who created this great nation; Lincoln, who saved it; and Roosevelt, who has done so much to perpetuate the comfort, the progress, and the prosperity of our people and the very perpetuity of the nation itself.

A nation such as ours, with all the great resources that have been and still are ours, can not help but be great. But if these resources be wasted this nation, like others that have gone before it, must crumble and fall into dust. You will remember that in the days of Him who was crucified the Holy Land was a densely populated country. Those of you who have traveled in it in these later days have seen how barren and droughty it is. In the old days its mountains and its hills were covered with forests. Those forests have disappeared and the land, barren and dry, supports only a scattering population of shepherds and nomads.

China in its day was densely forested in its mountainous regions. Every tree of those forests has disappeared. The rivers of China run riot, destroy thousands of human lives every year, and the land is arid because the people of that country have destroyed their forests.

A portion of Spain in the olden days was densely populated by a prosperous agricultural people. They cut from the hills the forests, and those valleys, once fertile and supporting a dense population, are now droughty, arid, and torn by the floods of winter and spring.

Portions of our country have suffered the same fate, and it lies in your hands, gentlemen of the States, it lies in your hands to cooperate with the National Government in order that those forests may be saved and the future prosperity of our children and our children's children may be preserved, in order that the nation may continue to be one of the great, if not the greatest, nations on the face of the earth.

We put on the uniform; we shoulder the musket; we follow the flag in times of war and do not hesitate to suffer and die for the benefit of our country. There are greater problems and crises than those of war. They are the crises and the problems of peace. One of those crises now confronts this country, as we of the West know better, perhaps, than you of the East and South. That crisis is of the greatest importance for the present and the future. It has to do with the salvation of the country through the salvation of its forests, and the salvation of those other great natural resources which have made and are making now, and will, if we save them, continue to make us great.

And that, as has been so well said here upon this floor, can only be done when the people of the States remember that, while the States are great, the American Republic is greater than them all—greater because the States could not exist free and independent without the nation.

MR. POWELL EVANS, MEMBER OF THE PENNSYLVANIA STATE CONSERVATION COMMISSION AND REPRESENTATIVE OF THE AMERICAN AUTOMOBILE ASSOCIATION.

Mr. EVANS. Mr. Chairman, speaking as an appointee of Governor Stuart, who could not possibly be here, it is the feeling of our state commission that we should like to return with more instruction as to the practical things for us to do as the commission of the State of Pennsylvania.

I called attention to this matter this morning in a resolution which was submitted to one of the members of the committee on resolutions, and he suggested that it be presented here now.

We understand, especially those who were here last May, as I was fortunate enough to be, the necessity of coordination in state work through this National Conservation Commission, but we are somewhat at a loss, as a state commission for the State of Pennsylvania, as to the practical form this effort is to take.

Our thought is that if we had a schedule of the necessities that each State now knows it has within its borders in line with this general movement; of the points at which national bodies asked here as conferees touch with this general movement; of the particulars of the conclusions of the commission itself, it would give us a bird's-eye view of the great conservation movement in its entirety for the United States, from which we could pick out the proper work to be done within our own borders.

Is it in order to read this resolution?

The CHAIRMAN. I am afraid that the chair will be obliged to rule, in accordance with the expressed will of the conference, that all resolutions must be referred to the committee on resolutions without debate. I am sorry that that must be my ruling, but I have been so instructed.

Mr. EVANS. I am sorry. I want to say one word here on a matter which is at present of importance in the State of Pennsylvania and to the American Automobile Association, and that is on the subject of good roads.

As I understand it, good roads are now supported in a measure by forest revenue in some States. The State of Pennsylvania is behind in that movement. I do not want to be considered as pleading for a special interest here in behalf of the American Automobile Association. Its work in this direction is in entire accord with the National Grange, a national organization comprising a million farmer members all over the United States. It is working in accord with the Good Roads Association, another body of private citizens.

We have in this country only about 8 per cent of our road systems that are improved comparably with any one of the western European countries.

It is proposed in our State, we hope in ten years, to spend something like $50,000,000 on that work.

The State of New York is now spending $5,000,000 a year—$50,000,000 totally.

The State of New Jersey has been doing the same work.

A convention of six governors and their advisers, in New England, recently met largely to consider this question. The difficulty is that unless the movement is coordinated through some such agency as this the money is not properly spent when it is provided. There is not a uniform knowledge of how to build good roads in principle. The practice must vary with the minerals and with the character of the soil. There is no uniform legislation regarding road use. It is the feeling of this body which I represent that it is strictly within equitable and constitutional limits that interstate travel over highways should be governed by interstate laws, and not by a different law in every one of the 45 States.

A farmer of the borough of Sewickley, in the State of Pennsylvania, once told me that he "did not object to using four horses to pull a load of milk up the hillside in winter, but it was going too far to use four horses to pull the load down the hill." That is the condition of much of the highway all over the United States.

I hope to see this commission come in touch with the practical necessities of the people in many phases of economic work and thrift like the above, which do not lie strictly within the borders of the great subjects of mining and forest preservation, however important they may be.

I thank you.

COMMISSIONER JAMES S. WHIPPLE, OF THE STATE OF NEW YORK.

Mr. Whipple. Mr. Chairman, ladies, and gentlemen, I am so very much interested in the preservation of the forests of the country that I am not willing that even roads shall interfere with it.

I am very much in doubt whether a plain, practical man ought to take much of the time of a convention like this where there seem to be so many scientific men; but to me it has always seemed that what we call in western New York "common horse sense" is so much better in working out a difficult problem than, sometimes, technical knowledge alone is, that perhaps you can stand for a little just now.

Forestry in this country is very young—practical forestry.

I have listened here for two days, and I listened last spring at the other conference for two days, to splendid things said and great thoughts propounded; but very few men have suggested remedies that seem to me we could apply and do something.

The paper on forestry read this morning is a fine report, but I have to say, Senator Smoot, that you left out the one great, important thing, and I hope you will pardon me for saying it——

Senator Smoot. Certainly.

Mr. Whipple. You have not said a word about how to reproduce forests, practically.

Now, it is all nonsense to talk about our having forests enough by natural reproduction, and you all admit it. You may say that we are cutting off our forests, some of you say this, three and a half times faster than nature produces them. If that is true, that is the whole proposition, is it not? How long is it going to be before you have no forests, however carefully you handle them?

The gentleman from Alabama thinks that they have forests enough, if practically handled, to take care of the interests down there for some time; but do you not know that we are cutting 40,000,000,000 feet, board measure, each year out of the United States forests, and that 1,500,000,000 feet of that are taken out of my own State's forests? If you will look at the charts you will see that that is a small part of it when we consider the loss by fire and insects, yet that is more than three and one-half times the growth. If you admit that fire is sweeping away more than you cut, and one-third of what you cut is loss, and your population is increasing so fast that in fifty years you will have 200,000,000 people in America, and the demand for timber is increasing faster than your population, and the supply is decreasing much faster than either, what are you coming to in America? The questions I am asking are, what are you going to do about it? How are you going to prevent it? What are your remedies? No one has told us.

You are using 2,000,000,000 feet, board measure, for newspapers alone.

In the State of New York there is standing to-day only about 41,000,000,000 feet of saw timber. We are cutting it five times as fast as it is produced. The State owns 1,600,000 acres of that timber land that must be deducted from the calculation because of our constitutional provision. What is our situation? In twenty years, at the rate we are going, not one sawing stick will stand in the State of New York; and we are getting 85 per cent of our pulp wood from Canada, even if our good friend does insist that some lumber goes back to Canada.

What is the remedy? That is the question. We can not take it out in resolutions and talk; we will have to do something.

We have got to get out, every mother's son of us that has an acre of land that is not good for agricultural purposes, and plant trees. It won't do to set it aside to the National Government and the States as forest reserves alone; we must economize in every way possible; but, above all, we must plant trees.

Germany has planted trees for a thousand years, and all of its forest is a planted forest. The German people produce 100,000 feet, board measure, all told, upon a single acre. The best timber in this country, east and south and west, until you get to the great trees of the far West, will not run over 20,000 feet to the acre. We have got to be practical; we have got to use this common horse sense. What ought you governors to do? Allow me to speak just as plainly as I can, in the western New York way. Go home and establish a commission, if you have not done it already, and put a Pinchot at the head of it.

Then furnish it money, and don't get down on your knees, or anywhere else, and implore the National Government to set aside some state land in a national forest; do it yourselves. You may kneel at this shrine for years and you won't get it done. The way to do it is to do it yourselves. It is in your own hands.

Get a little state forest preserve, and then handle it in a practical way. Don't do it as we are obliged to do under the constitution of the State of New York; that is, let it stand there and rot and burn up, and we not able to take out a single stick. We will have to amend our constitution.

Be practical about it! Then build some tree gardens and put your last dollar into it, that you can raise. Plant every year some millions of pine trees. Hard woods reseed themselves; they come up from the sprouts; but the coniferæ in this country must be planted, as every practical man knows. You sweep away a pine, spruce, or a hemlock forest and it will never grow again; those trees must be planted. In Canada and some other places they do reforest pretty well, but not in our country. Be practical. Don't do so much wishing and resolving, but do business.

The next thing you want to do is to go among your people; go out as missionaries among the people. Do not get it into your heads that all of our people, not even our legislators, know about this business, for they don't know about it. None of us have known much about it except for a few years.

Just think! In 1885, in the State of New York, the first commission in the United States was organized. At that time not one single educated forester lived in the United States that anyone knew about; not one forestry school existed at any college of the United States. Twenty-three years! It took us twenty years to do the preliminary work, and it is only within the last three years that we have aroused the whole people in the State of New York. How did we do it? We got out among them at their homes and made speeches; told them of this wonderful cut of timber and the great amount it was over the natural reproduction. We told them of the history of China and of France and of the other countries where their timber has been swept from the hillsides and the land denuded and made worthless for agricultural purposes, as the governor from California told us a moment ago.

The **Chairman**. You have two minutes more remaining.

Mr. **Whipple**. I wish I had thirty minutes more, to get some practical things into the heads of the members of the congress. You can not have a country worth living in without forests, and the proof of it is the history of the whole world. You cannot have your water running in even flow from the uplands without forests.

You are talking about conserving forests. New York City is spending $150,000,000 to build a reservoir at Kingston to get water for the 4,000,000 people in the city of New York. If New York City does not protect the trees upon those historic hills, the Catskills, that reservoir will not do all that is expected of it, and they will have to go somewhere else for part of their water supply. Why? Because when you destroy God's reservoir under the trees man can never build one as good. It takes that natural reservoir to keep and hold the water, and you can only maintain that on the hillsides by keeping the trees there. Therefore their money will be spent in vain unless the trees are kept there.

Some one in the report of this commission has said that there is as much water as there ever has been, and that we could not create water. Those men that drew the original report of this national commission are mistaken. You let a spring dry up on a mountain side because you have taken the trees away. That water is gone. It has disappeared from thousands of our springs to-day. But you reforest that hillside and you will reproduce the water. Those springs dry out because the forests are gone, but you reforest the hillsides and the water will come back. There is too much to the subject for any man to undertake to cover it in ten minutes.

A **Delegate**. I move that the gentleman's time be extended by unanimous consent.

(The motion was numerously seconded.)

The CHAIRMAN. Is the request that the gentleman's time be extended ten minutes?

A DELEGATE. Yes.

The CHAIRMAN. Is there objection to extending Mr. Whipple's time for ten minutes?

(There was no objection, and it was so ordered.)

Mr. WHIPPLE. We have to have forests in the country, ladies and gentlemen, because of a hundred things. First, they affect the climate, they affect the rainfall, they are valuable to the agricultural lands. Without forests in a rolling State like New York or like Pennsylvania you can not have producing agricultural land. Am I not right?

A VOICE. Right!

Mr. WHIPPLE. If water is not absolutely necessary to good farm lands, tell me why it is that the arid lands of the West do not produce without it. Tell me why it is when you pour a little water on the arid lands of the West, where stump cactus grew, and that only, you can produce 50 bushels of wheat to the acre. Tell me why it is that the far-famed, beautiful valley of the Euphrates, which we have heard so much about in song and story, once as beautiful as a dream because of its forests and streams, is to-day a howling waste. Simply because the forest trees were cut away and the waters dried up. We must have water. We must have the forests in order to have the water.

Kansas, Ohio, Indiana, or any level State, do not need the forest trees for agricultural purposes so much as we do in New York and Pennsylvania and the East. Why? Stop and think. In New York State all but four of the great rivers of the State head in the Adirondacks and Catskills—in that 2,000 feet elevation, upland plateau. The streams, when not protected, run rapidly away and the water is wasted. It does not even have a chance to evaporate. But on the level plains of Kansas it falls upon that flat land and it soaks into the ground, it saturates the soil, it produces moisture necessary, for weeks and for months, for the crops to grow upon the land. We must have the forests. You can get along out there if you don't have so much forest.

So it is rather a local question in respect to the farm lands of the country. We have got to have forests because of the healthfulness of a country. Do you not know that the forest trees are constantly pouring off into the air great quantities of oxygen; that they take up the things that are poisonous to your life and grow upon it; and that they furnish that which we must have? Do you not know that they have a wonderful effect upon the temperature of the country? Can anyone tell me why it is 25 degrees cooler in July at Lake Placid or Saranac than where I live in the Alleghenies, in the same altitude, 200 miles farther south? Nothing in the world except that splendid great forest that covers that upland in the northern part of the State of New York.

Let me make it perfectly clear to you by the simplest illustration. If forests are not as valuable to a country as I say, what would be the condition if to-day, through some great force in nature, every tree and shrub should be swept from the face of Pennsylvania or New

York State? Would not chaos reign to-morrow? Would not the home of every wild bird and every wild animal be destroyed; would not every stream be uncovered; would not the surface of the land be like the roof of this building for the water to fall on it and run immediately to the stream and down to the great sea and be lost forever? Would not the price of agricultural land in those two States depreciate in fifty minutes 50 per cent? If it would not, then the history of China is a lie; then the history of France is false. Three hundred years ago France swept its forests from its hillsides; its land was eroded and washed into its harbors. If it is not so, then France has spent $200,000,000 since then to reforest those mountain sides for nothing.

The country that does not have forest growth is like a house without a roof, uninhabitable and worthless to the people.

You may talk about preparing your Mississippi for transportation of the products of the country. You may talk about the conservation of your coal and iron and gas and oil, and all that. Coal, iron, gas, oil, and other minerals are only created once in the creation of the world, and all you can do is to handle them as carefully and as economically as you can; you can not replace a pound of them. But your forests, the great objective point, it seems to me, may be restored, must be saved, and you can only save them by careful handling and by planting.

Now, go home, get your commissions to furnish the money. Build your tree gardens. Go among the people and encourage them to plant trees and relieve their land that is dedicated to forests from taxation. Encourage your people. Give them the trees free. Let the State furnish its people with the trees free of charge, in order to encourage them, and then relieve them from taxation on the land dedicated to the forests, and you will get every farmer raising trees.

Think of what New York is doing. The pioneer in the work, twenty-three years old, held up sometimes as an example. We are doing a lot of things that we do not ask the National Government to help us in. We know we would not get its help. We are going to take care of it ourselves. We are spending $500,000 $600,000, $700,000, $800,000, $1,000,000 a year in buying land, and we are going to keep it up.

But get your farmers to planting. We are building tree gardens all over the State, raising millions and millions of pine trees. We don't plant the poor kinds of trees. We get the best commercial tree, that grows the fastest. The hardwoods will take care of themselves if we let them alone and keep the cattle out. Plant pine trees, plant spruce trees, plant in the South the tree that grows the best there and is the best commercial tree. But all of you have got to plant trees.

As I have said, our State is the pioneer in this, yet we are asleep in America on this question. We have to get practical and get down to business and plant trees or in twenty years our children will curse us for our negligence.

GOVERNOR JOHN A. JOHNSON, OF MINNESOTA.

Governor Johnson. Mr. President, I simply want to rise to ask a question. I think I probably grew as enthusiastic listening to the remarks of the gentleman who has just spoken as any other person in the room, and I was impelled to applaud probably as rapidly and as frequently as any other man here, and it is a nice thing to sit here and be told that you don't understand this question and we want to give you the practical results. Now to my mind I want to ask the gentleman what is the remedy? After all—I may have been obtuse myself, and there may not have been any ambiguity in the remarks made—but what is the remedy? Plant trees! I heard that in May last year when we had that conference, until I got black in the face. I have heard it in my country for ten years. And this thing of going back home and planting trees is all right; we have got to plant the trees. But the governor does not own the farms of the people of the State of Minnesota, and the governor of North Carolina does not own the farms of the people there, and it is the same way in every other State. The governor does not own the great lumber areas that have come into the care and watchfulness of the great lumber barons of the country, and he can not plant trees on that land, and he can not go home and make the legislature do anything he wants them to do with the public moneys of the State, because the legislature in the State is the custodian of the public moneys of the State, and that is so in every State in the Union. So it won't do to say you do not need the interest of the National Government, and the gentleman who has just spoken confesses at the conclusion of his remarks that he is going to plant two or three million trees a year, and he says that they are cutting down more Christmas trees in the State of New York than they are planting each year.

We do want these discussions, we do want all the information we can get, and I was very glad that the last speaker spoke of the matter of exemption from taxation as an encouragement to the planting of trees. It is about the only reasonable suggestion I have heard here.

With regard to the matter of forestry, without desiring to introduce his name, I think there was suggested at the White House at the conference there in May the best suggestion in the way of forestry that was made there or here. Unfortunately it introduces a political question. Are we going to avail ourselves of the vast areas of Canada by reciprocal trade relations, or are we going to continue that barrier in the way of an imaginary line, which will not permit us to bring in the Canadian lumber as a means of protecting our own lumber?

I know full well that there are men here attending this conference who are personally interested in the manufacture of lumber in America who are going to do all they can to make this country refuse to take any action looking toward the bringing together of the great Canadian and great American interests, and I hope the conference will be big enough to look over the heads of any men who have a personal interest. What will take the place of lumber? I have formed a great affection and regard for the gentleman who some time lived at Skibo, if that is the proper pronunciation, because I believe that in the introduction of steel he has done more to preserve the forests than any other individual in this country.

We have got to go home and talk to our people, and I am going back to talk to mine. Appoint a commission? That is good. We have got conservation commissions in the national way. This, in a sense, is a commission. Let it go back and reforest America—this handful of people. This discussion is good in the matter of education. No one in my State thought of it ten years ago. No one in my State thought of the enlargement of the Mississippi River ten years ago. No one in my State thought of the erection or construction of canals through the central basin ten years ago. But it is because of the pioneers, if you please, who blaze the trails of public opinion, that all these things are made possible.

I would be glad to have a specific and definite remedy. In my judgment we have got to retrace much of the ground we have already lost. I know something about governmental reforestation in my country. I know something about the preserves where 10 per cent of the trees must remain. In my judgment, Mr. Pinchot, that is absolutely a failure, because the 10 per cent, lacking the protection of the surrounding trees, either dies, breaks down, or eventually gives way.

It seems to me it would be better to preserve great tracts of trees. But there is so little that any of us know—even, I think, the expert from the State of New York, who failed to give us a specific remedy for the reforestation of the country—that we all ought to be willing to learn, and I would like to be able to take home one great big idea and say to the legislature, "Do that." And if the gentleman from New York will give me the opportunity to do it, I will be his servant forever.

Mr. WHIPPLE. A question has been asked. There are so many ideas to give that it is hard to sort out the ones that we can advance and have take effect in so short a time. Let me give the gentleman an idea.

We believe, in the State of New York, and we are going to put it in operation this year, that the State has the power to control the cutting of timber on private land; that is, to prevent denudation, also the clearing up of the débris, and so on. We are going to put that into the statute.

Mr. JOHNSON. I would like to ask whether that is a fact—that the State of New York, or any other State, has the right?

Mr. WHIPPLE. The Supreme Court of the United States has said so, as cited by your President in the May conference. There has been a decision by the state supreme court of Maine to the same effect more recently.

Mr. JOHNSON. I may be wrong, but I did not think the Supreme Court had decided that—that is, the Supreme Court of the United States.

The CHAIRMAN. I think it was the supreme court of Maine.

Mr. WHIPPLE. But underlying constitutions, there is in the police power of the State the power to do that which will protect the whole people——

Mr. JOHNSON. I would like to know what is the actual fact about that decision. Mr. Pinchot says that he thinks that was the supreme court of Maine.

Senator SMOOT. I think the last point the gentleman has reference to was a decision by the Supreme Court of the United States, as I remember it. The decision of the supreme court of Maine was upon the other point.

Mr. **Whipple**. There was a question that went to the Supreme Court of the United States on the question of whether the State had the power to regulate the use of private property for public good. It was the case of the Hudson Power Company and arose in New Jersey, in order to protect the people in the lowlands in the matter of the water flowing over their lands, as a general public necessity. That was the case, if I remember the title correctly. There is also a case to the same effect in Massachusetts, where the court said to regulate was not taking.

The practical working out of it in our State. Mr. Johnson, is solved, I think, in this way. We got last year a great many farmers to plant trees. As I said, the State can never plant enough, because the cut is so great you can not keep up; but if you get every farmer to planting trees, and we are giving them trees now at cost and will next year give them absolutely free—if you will do that and then get your foresters to show them how to plant the trees and get every farmer on every farm to take an interest in this work you will be able to accomplish something. Our farmers are getting enthusiastic about it.

Mr. **Johnson**. You speak of getting the farmers to plant trees on their farms. In the States of Wisconsin, Michigan, and Minnesota there are millions and millions of acres of land that have been cut over, and they are not farms at all; it is not farm land, it is a sandy soil. What are you going to do as to that kind of land that is not farmed and will not be farmed for years to come?

Mr. **Whipple**. There is a lot of land in New York, too, that is poor land and has been worked out. It is sandy, poor land, and not good for farming. We think the State should acquire that land. We have a commission to buy land, which commission is always in session, and we are buying about a hundred thousand acres a year. We have 1,600,000 acres now, and we are going to buy 2,000,000 acres more and reforest it. That is what the State is doing. Some of the poor sand lands are only worth $1.50 to $2 an acre, land on the Upper Hudson and in the Adirondack country, but forests can be planted on that land, and forests are growing there now in the finest kind of way. And so with your State. Your State should acquire that land you speak of, in my judgment, and you can raise enough trees on it to support the needs of your State. That is what Germany has been doing. Many of its little villages have been planting trees, and from those trees they are able to pay their taxes and supply all the lumber they want. We must be able to do that if the Germans can do it.

Mr. **Johnson**. There are lots of things we do not know as much about as the Germans do.

Mr. **Whipple**. Well, we must get at it, then. If there is any other specific question——

The **Chairman**. May I ask your indulgence for one moment. There is one suggestion I want to make to Governor Johnson and all the other governors here and perhaps this is a good time to make it. It seems to me that if each State could do what Alabama and Oregon and a half dozen other States are doing, and take stock inside of their own properties, of their own resources, exactly as the national commission has been taking stock of the national resources, we should get a body of information that would be of the utmost value.

I believe that there is nothing more important for the States to do than to make a study of their own situation through their state conservation commissions.

Senator SMOOT. I simply want to say that I hope none of you will rely on being able to get lumber from Canada in order to save our own forests. I have been in Canada, through their forests, and I think if we ever put lumber on the free list, as suggested by the governor of Minnesota, with the idea of getting lumber from Canada——

Mr. JOHNSON. Excuse me. I did not use the term free list. I simply thought there might be some arrangement that might allow us to bring in our Christmas trees, anyhow, while the other trees were growing. Excuse me, I have to leave.

Senator SMOOT. If you will confine it to Christmas trees, all right, I will not have anything to say.

EX-GOVERNOR NEWTON C. BLANCHARD, OF LOUISIANA.

Governor BLANCHARD. Mr. Chairman, on the question that was raised by the gentleman from New York, as to what the power of the States may be in respect to controlling the cut of timber lands embraced in private holdings, I desire to say that that question has occupied the attention of the governors of some of the States, and perhaps all of them, for some years.

In my message to the general assembly of the State of Louisiana in 1906 I recommended the enactment of a law that would prevent the holders of large bodies of timber lands from cutting any trees under 10 inches in diameter. I urged that they be required to cull the trees, cutting only the larger ones, and leave growing the smaller ones, in order to perpetuate the forests.

Before putting that proposition up to the general assembly, I consulted eminent counsel as to whether or not there were constitutional difficulties in the way. When I presented it to counsel, he shook his head and said, "I fear there are such difficulties." I replied I thought not; that in the question was involved a great public policy, and wherever there was a sound public policy involved authority would be found to sustain legislation in aid of it.

The lawyer consulted was asked to examine the question, and in a few days he returned to me saying that my view was correct; that he had found authority to sustain the legislation I had recommended. I had him prepare a bill, which was introduced in the senate of the State, but it failed of passage. The timber lobby was too strong for it.

It will be remembered that when the governors were in conference with the President at the White House in May last, the President stated in his admirable address that the legislature of the State of Maine, having the right under a custom there obtaining, to ask the supreme court for an opinion upon a proposition as to the constitutionality of which they were in doubt, certified to the supreme court of Maine, the very question that we are now discussing, and that court returned an opinion that the authority was in the legislature to do the thing desired.

And in the discussions that took place at the White House upon the occasion of the conference it also appeared that the question was brought up in a New Jersey case that went to the Supreme Court of the United States, not upon this identical question, but one akin to it and involving the same legal principles, and the Supreme Court affirmed the power to be in the legislature to do that which had been done.

Mr. Chairman, another important question affecting the conservation of the forests is that discussed briefly in the report and alluded to in the speech of our distinguished friend, the Senator from Utah, this morning, and in other addresses. I refer to the policy of taxation looking to encouraging not only the maintenance of growing forests but the reforestation of cut-over lands. The importance of this can hardly be overestimated.

In the report that was read here on the first day of the conference, it was suggested that the lands be assessed for purposes of taxation as though there was no timber upon them, and then when the timber is cut and passed through the saw to tax the output of the mill. That system commends itself to me. Under the present tax laws of many of the States large assessments are put on timber lands, and this is forcing timber holders—the owners of the sawmills—to cut off that timber too rapidly. At least it is having much effect that way. Give them the encouragement to hold back and not force their product upon the markets, and then exempt, by a system of wise tax laws, cut-over lands devoted to purposes of reforestation.

A word or two more, Mr. Chairman, and I will be through. The former governor of California (Mr. Pardee), who a little while ago addressed the conference, referred to three great Presidents, Washington, Lincoln, and Roosevelt. What he said as respects the three I subscribe to, but there is another who is entitled to a place in the front rank. Presidents are to be judged by what they accomplish for the great good of the country they rule. Washington was the grand leader of the forces that founded the Republic. Lincoln was the great leader of the forces that prevented the disruption of the United States. Roosevelt has given magnificent policies to his country, and has pushed it forward enormously in development and added greatly to its prestige and influence among the nations of the earth. He is the President who has exerted that force which is about to realize the dream of Columbus—Columbus, the greatest dreamer of the ages. It is the dreamer that conceives great things. The practical man of affairs comes along and takes them up and works them out. Roosevelt, in this instance, is that practical man. Columbus dreamed of a near passage to the East by way of the West, and inspired by God he crossed the Atlantic Ocean in his three little caravels and landed upon a West Indian island, which blocked his way to the Isthmus. But for that island, and had he escaped the peninsula of Florida on the one hand and the island of Cuba on the other, he would have reached the Isthmus, to cross which was necessary to that "near way to the East by way of the West." It would have barred his passage. We in this day and generation are accomplishing the dream of Columbus. The great nation established on the continent he discovered is doing it. We are cleaving through the Isthmus a water passage. The completion of the Panama Canal is in sight, and when it is cleft through the Isthmus the dream of Columbus will have been realized and our country and the world pushed forward hundreds of years in civilization.

And some day, after this great work is accomplished, upon the two highest promontories along the line of the canal, the American people should erect two statues of heroic size, one commemorative of Columbus and the other of Theodore Roosevelt.

But, Mr. Chairman, I said that there was another great President entitled to be added to the list. A few years ago I made a pilgrimage to Monticello, near historic Charlottesville in old Virginia, and with uncovered head stood at the tomb of Thomas Jefferson, and on the modest shaft of granite that rises over his grave I read this inscription:

> **Here lies Thomas Jefferson, the author of the American Declaration of Independence, of the statute of Virginia for religious freedom, and the founder of the University of Virginia.**

This epitaph was written by himself. It was found among his papers with directions to place it upon his tomb. He had been the recipient of great earthly honors. He had held high stations—minister to France, governor repeatedly of Virginia, and twice President of the United States. But he discarded all these and chose to rest his claim upon posterity to greatness to the three mentioned.

Mr. Chairman, he should have added another. Certainly one of the greatest of his achievements, and which alone would have entitled him to a position in the front rank of Presidents, was the consummation of the Louisiana purchase, by which territory was acquired now forming fourteen great States of the American Union.

If George Washington founded the Republic, Mr. Jefferson, coming shortly after him in succession, doubled the original area of the Republic, gave it dominion from ocean to ocean, and made it possible for Columbia to become, as she is today, the torch bearer among the nations of the world.

PROF. FRANK W. RANE, OF MASSACHUSETTS.

Professor RANE. Mr. Chairman, I simply rose to say that as chairman of the conservation commission of Massachusetts, we are hand and soul in this work with you. I realize it is impossible to discuss all the various points that have come out in this convention. We are here, however, I am sure, to get the backbone of the whole discussion and take it home and get to work.

Recently we have had in New England a meeting of the New England governors, people interested in the subject of forestry and conservation generally throughout that particular section of the country. Recently a meeting of the forestry officials of the six States of New England was held. At this meeting we have discussed and gone over the matter of doing something that we can take to our various legislatures this year, which we hope will bring results. I think forest fires with us in New England is one of the worst difficulties we have to deal with, the question of having some mandatory conditions whereby we can stop fires being extremely important. That is one of the things we are first to consider.

We have been taking up the subject with the railroads and with private individuals, but more particularly getting a definite system of usefulness. I find that there is just as much trouble between our various towns in Massachusetts as there is between various States, and it is necessary to bring them together. We have a system in our own State of Massachusetts whereby we appoint forest wardens in each town. These men are appointed by the selectmen of the town, subject to the approval of the state forester.

From one year's experience I believe that that is going to work out well. With 321 men in Massachusetts representing local conditions, if we can educate those men to be public spirited, to represent their towns, to take back the idea of the State's interest and the nation's interest, we have a natural channel of usefulness. Now, if we can stop fires we can stop them by the individual man on the spot. This man has the privilege of appointing his deputies and discharging them. He has police powers, and he is giving to the State data in regard to fires, the number of fires occurring, the amount of damage done.

Through this natural channel I believe we are going to get to the subject of taxation. We are going to get to the subject of reforestation. I think the natural channel will be found in this way whereby we can touch the man that is really going to do the thing. In Massachusetts we have gotten in touch with our railroad people. They are as much interested in the subject, I believe, as any people, and I believe in New England they are going to take hold of this thing, hand in hand.

We had a resolution, passed last week, that I would like to read if I had the time, but it will be published.

I thank you for this opportunity of representing Massachusetts.

(Thereupon, at 12.35 o'clock p. m., the conference took a recess until 2.30 o'clock p. m.)

THURSDAY AFTERNOON, DECEMBER 10.

The Joint Conservation Conference was called to order at 2.30 o'clock p. m. by Chairman Pinchot.

The Chairman. We will begin what I anticipate will be the concluding session of the conference, so far as any program has been laid out. We take up this afternoon the subject of "Waters," and at some time during the afternoon will probably hear the report of the committee on resolutions.

Ex-Governor Pardee. Mr. Chairman, permit me to move that the report of the committee on resolutions be made a special order this afternoon at 4 o'clock.

(The motion was duly seconded, put, and carried.)

DR. W J McGEE, SECRETARY OF THE SECTION OF WATERS, NATIONAL CONSERVATION COMMISSION.

The Chairman. We will now take up the subject of "Waters." Mr. Burton, chairman of the Inland Waterways Commission, has unfortunately been detained and will not be here to make the opening statement. I will therefore call upon the secretary of the Inland Waterways Commission, Doctor McGee, to take his place.

Doctor McGee. Mr. Chairman and gentlemen of the conference, I shall do no more than ask attention to a few primary ideas with respect to our waters.

In the first place, I should like to emphasize, and have you all join me in emphasizing, the great fundamental fact that water is a resource. Hitherto it has not been our custom to regard water as a resource of a definitely limited quantity. We have been accustomed, after the manner of the ancients, to think of the four elements, of which water is one. We have been accustomed to think of it as free and abundant as the air or the light of the sun, or the wide amplitude of earth. Now, the primary idea which I desire to impress is this, that there is just so much water and no more. In this connection it is necessary also, as I conceive it, and as I hope you all agree, to apply the quantitative method in dealing with water, the same method which we employ in dealing with coal, or iron ore, or any other resource. That indeed is requisite to a clear idea concerning water as a resource—water of which there is only a certain amount and no more. The application of the quantitative method is absolutely essential.

In the report of the National Conservation Commission, which you heard read yesterday, the quantity of water and the sources of the water with which we are blessed were set forth in considerable fulness, I shall not trouble you by repeating the figures in detail. Merely to render clear the primary idea of water as a resource—and I am referring, of course, to fresh water—let us have it in our minds that the sole source is the rain which descends from the heavens. That boon, after reaching the surface of the earth, is divided; half of it is reevaporated, and a portion of this half may be reprecipitated as rain; but we need not follow that half further than to say that after reaching the surface of the globe it is evaporated. One-third of the entire amount flows down to the sea through the rivers, of which many are navigable. There remains one-sixth, and that is consumed or absorbed. On that one-sixth, in the last analysis, depends the habitability and productivity of our country, of every acre of our farm land, and of every acre of our forest land. Nor do we often realize how large a quantity of water is consumed in plant growth and in animal existence. We seldom realize that each average adult man of 150 pounds takes into his system in the course of each year no less than a ton of water; we seldom realize that on the average each bushel of corn requires in the making something like 15 or 20 tons of water. This is an illustration of the fundamental importance of water to the productivity of our land.

Now, to return for one moment to the quantity of water which we receive from the heavens as rainfall. An average of 30 inches over the entire length and breadth of the land, or a quantity equivalent to 10 Mississippi Rivers, is all we have. Without it no acre of our land would be habitable. Without it no industries could exist, and without that one-sixth of it which is largely consumed and absorbed in vital processes the land would be unproductive and sterile, and unfit to form the home of human kind.

The effective fraction of the water descending from the clouds is not that which flows off over the surface during storms; on the contrary, it is that which seeps into the earth in such fashion as to form ground water. Let us have clearly in mind this idea of ground water as a part of the great resources made up of water. How much ground water have we? Of late we have been considering the matter with some care, and we estimate that within the first hundred feet of the surface there is an accumulated body of water, which ought to be but is not quite permanent, equivalent to a reservoir 16 or 17 feet in depth, spreading over the 3,000,000 square miles of the area of our land. That subsurface reservoir is the value on which we must depend for agricultural production, forest maintenance, and the development and continuation of all our industries.

When we speak of that vast reservoir spreading from the Atlantic to the Pacific and from the Lakes afar north to the Gulf on the south; when we think of that stock as the real source of water supply for agriculture and all other industries; when we think of it as the sole source of all our streams, which are fed slowly by seepage through the ground as springs or otherwise; when we think of this reservoir in its extensive applications and endless relations, we must realize that it is no less a national and interstate possession than the air itself. It belongs to all of us. It is the common property of the entire people. And there are those of us who conceive that it must be so administered, and that, proceeding from the navigable streams which we hold should be so improved as to relieve the traffic congestion of the country, we should deal at one and the same time with every aspect of this great resource on which the value of all the rest depends. It is a national possession, and the possession of the several States jointly. The States hold an undivided interest in this great commodity.

This, Mr. Chairman, may suffice to get before you a great subject. I desire only to add that Governor Noel, who is on this platform, Governor Ansell, Governor Deneen, who will arrive shortly afterwards, and Governor Hoggatt, of Alaska, are among those who have the courage to express the convictions of their respective Commonwealths concerning the value of this fundamental resource; nor may I neglect Governor Stubbs, of Kansas, the central State of the nation. We are hopeful also that the chairman of the Inland Waterways Commission, Mr. Burton, will shortly be with us.

I thank you, Mr. Chairman, for the attention that you and the gentlemen present have given me.

GOVERNOR WILFORD B. HOGGATT, OF ALASKA.

The Chairman. In the over-richness of our material in respect to governors I find myself embarrassed, and the only ray of light I can see is to pick the governors who have not yet spoken and give them an opportunity to speak before we call on those who have spoken once. I see Governor Hoggatt, of Alaska, and will ask him to favor us with a few remarks on the subject of waterways. I take pleasure in presenting to you Governor Hoggatt, of Alaska.

Governor Hoggatt. Mr. Pinchot and gentlemen of the conference, this comes somewhat as a surprise, because I am here simply to learn some things that may be of advantage to the country of which I have the honor to be the executive officer and which we may use in the dim future. Most of these questions which are of vital importance to the older States have not yet assumed any importance with us. We have not begun to cultivate the soil, except in very limited quantities, for the purpose principally of furnishing garden truck for our mining camps.

Nature has provided us with a magnificent system of waterways along the coast of Alaska to give us what we need in that respect, and has also given us a river equal in volume, size, and navigability to the Mississippi to bisect the great northern region belonging to the

United States. This river is fed largely from the glaciers remaining in the mountains which divide the coast from the interior valleys, and from those between the Yukon Valley from the Arctic Ocean. Until the glaciers disappear we will have plenty of water in the summer time and lots of ice in the winter. There are some matters which are of great importance to us, which we have taken up and already begun to consider in the line of conservation. The first thing of importance is that of the forests. We have a large area of our country now embraced in forest reserves. We are working out a system by which we can utilize this timber to the best possible advantage and at the same time secure an ample supply for the future. We are confronted with rather a peculiar condition as far as the forests are concerned, and that is that our timber is of such age and growth that a great deal of it has gone to waste from nonuse. One of the most important things is to find some way by which we can use the timber that grows on the coast side of the mountains of Alaska before it reaches the point where it begins to deteriorate. I have noticed in my own experience that the trees grow to a fairly good size and then begin to decay at the heart. We have to find a use for those trees before they begin to decay, or all the strength of the soil will be exhausted by the timber and then no use made of it.

Another thing we have begun to take in hand is the matter of coal. We have found that we have large and splendid deposits of coal. We have it of different grades scattered throughout the whole Territory. In two fields we have bituminous coal that in analysis and steaming qualities is probably equal to anything found in West Virginia. We are endeavoring to find some way by which we can utilize these coals for the present and conserve them for the future without creating any monopolies, and yet reserve all the rights that are proper for the Government without hindering the efforts of our people in developing the field. We are on the road to success in this direction. Of course we all know, as the report of the commission stated, our metal resources are there; and when once used, they are gone forever.

We hope that when the metal resources of the States are largely a thing of the past we will have some left to supply the larger population of the United States.

I thank you, gentlemen, for your attention.

GOVERNOR-ELECT W. R. STUBBS, OF KANSAS.

The CHAIRMAN. Reference has been made by the last speaker to Governor Stubbs, of Kansas. I know we shall be very glad indeed to hear from him, and I will ask him to come forward and address us. I take pleasure in presenting to you Governor Stubbs, of Kansas.

Governor STUBBS. Mr. Chairman, ladies, and gentlemen, when I accepted the chairman's invitation to attend this conference, I did so with the intention of coming here to listen and to learn, and had no idea of having anything to say on the subjects that were to be presented to you.

However, the problems that have been discussed in this conference, in my humble opinion, are of greater import to the American people than any subjects that will be legislated upon in the halls of Congress during this session or the session that is to come.

This subject of waterways and the improvement of the great canals and rivers of this nation has been talked to death. What we need now is action; let us do something. There is not a man in this audience who has considered this subject who does not know that when the States of America ratified the Constitution that we have adopted, they gave exclusive control of these great arteries of trade and commerce to the Federal Government. He knows that this Federal Government, when it accepted this trust, accepted a responsibility from which it can not escape, and that means the development of these arteries, these rivers, these lakes, these harbors, and these canals. For more than one hundred years it has neglected its plain duty and obligation to the people of this great nation. It is no longer a question of knowing what to do or how to do it. There are hundreds and thousands of men who know all about it. It is not a question of material. We have all kinds of material. We have the waterways. We need the money that is necessary to develop these great waterways. It is not necessary for me to talk to you about the benefits that would come to commerce and trade if we had the Mississippi River and its tributaries, including the Missouri, developed with a 14-foot channel—1,500 or 2,000 miles of the Missouri and up the Mississippi as far as we can possibly go.

Such a movement would reduce the cost of transporting heavy traffic at least 70 per cent. The men who have investigated this subject say that the cost would be one-sixth; I will say that the cost would be one-fourth, to be sure to be within proper limits. Waterway transportation means one-fourth of the cost necessary to haul heavy traffic as compared to the present cost by rail. What would that mean against the present condition? What would it mean to Kansas with her 90,000,000 bushels of wheat, sending it down to Kansas City, together with other grain and grain products, if the cost were one-fourth what it now is? What would it mean to Kansas City and Omaha and the cities along the Missouri River, all the way up that great valley, if they could have coal come in from Pittsburg at 50 or 75 cents, or even $1, a ton, and pig iron from Minnesota for one-fourth or even one-third of the cost at this present time? It would not interfere with railroad traffic.

You have heard Mr. Brass tell how in Germany the great waterways haul millions of tons of heavy freight, and that there are railroads on either side of those great waterways that do more business than under any other conditions, that have more business than they can possibly take care of.

This is the greatest economic problem before the American people to-day. It is necessary only to apply simple, sound, business laws. Do you suppose if a private organization or corporation was going to build a transcontinental railroad, they would build a mile a year or 5 miles a year for one hundred years? Would they ever get anywhere with it in that way? In the name of Heaven, what does it mean that the great American nation, the greatest nation of the world, should dillydally and play like children with the greatest problem that ever confronted them in legislative matters? What shall we do, you ask? Ask me whether we can control the Missouri River—and I want to tell you briefly what I saw there.

I have been in the railroad-construction business for twenty-odd years before I blew into politics about four or five years ago. I had a minor part in building a great dike where the Missouri River was cutting pellmell into the south bank of the river there in Kansas. The water was 40 or 50 feet deep and was cutting under that black soil and coming up toward a great railroad track. What did we do? We threw out a lot of willow mats and sunk them with rock and built up a dike that has stood for nearly twenty years, and the great flood of 1903, during which occurred the highest water ever known in the Missouri River in fifty years, only made it stronger and filled it up on both sides.

I say to you there is no trouble about doing this work. It is not a question of how to do it. It is a question of getting the money to do it. You ask, How shall we do this great work? I say you can improve the Mississippi River all the way that it is navigable and the Missouri River for 1,500 miles and all of the tributaries of both of those rivers. You can improve your eastern rivers and your western rivers in eight years just as easily as in eighty years and then get some benefit out of them. How will you do it? Issue bonds at 2 per cent, and all you need to do is to authorize this broad-gauged, big-hearted Secretary Taft, who will be President next year, to go ahead and do this work like a great railroad company would do it. Do what the Congress of the United States did when they started to build the Panama Canal! They would have been a hundred years building that canal if they had put in a piece here and a piece there, and had no plan, no organization, no method.

You can establish a commission, you can put a chief engineer in charge of this great work, you can separate it into divisions, and it will be a mighty poor stick of a man who can not improve a thousand miles of the river, who can not improve all the necessary waterways to the Atlantic seaboard—and that is what we ought to have, right from the Mississippi up through this drainage canal to Chicago and on out to the Atlantic seaboard, as well as down to the Gulf of Mexico. I say to you this is a great problem which confronts the American people, and it must be solved.

What would it cost? Suppose you invest in this proposition a billion dollars, it would be a mere bagatelle in comparison with the benefits that would accrue. I heard Andrew Carnegie say yesterday morning that the benefits would be tenfold greater than the investment. Suppose you invest a billion dollars in the development of these great rivers in the Middle West, the Mississippi and her tributaries, at 2 per cent for fifty years; what would it cost? It would cost $30,000,000 a year for fifty years to pay off this debt. What would this great waterway pay in the way of return? Andrew Carnegie says the income would be $300,000,000 a year, or ten times as much as it would cost, and I believe he stated it conservatively.

What would be the result? It would build up great industries all along the banks of those rivers, develop our country naturally, and give us natural competition in the way of transportation. Are we going to do this thing in a businesslike way, as business people? Or, are we going to play politics and give every Congressman $50,000 or $100,000 for a public building, and give every man a job who wants one, and dole out the billion dollars or two billion dollars without any concrete results? I say to you I expect to see this nation go ahead under the administration of Mr. Taft—one of the greatest men who ever sat in the Presidential chair. I expect to see him finish up the greatest work that has ever been undertaken in the lifetime of the present generation, and that is the work that Theodore Roosevelt has promulgated.

It is a simple business proposition and there is no politics in it, and there ought not to be any politicians in it. It ought to be put on a sound business basis and under the control of good, sound, business men. It ought to be divided up into sections. It ought to be where the men who are now clapping their hands, cheering those sentiments, could see the great boats going up and down those waterways. It would interest us very much to know whether they might have waterway development in one hundred years from now, but I want to see it in my lifetime, and I expect to see it. I have two of the best-looking boys in this whole country, and I am willing to let them help pay the bills in forty or fifty years from now, and they will be glad to have the chance to pay the bills. I think Mr. Taft made a very happy remark the other day when he said it would do these youngsters good to have something to keep them under proper self-restraint. I think we could leave no better legacy to the American people than this great project at least partially completed, and if we do that, it will make this the greatest epoch in the history of the United States.

I thank you, gentlemen.

GOVERNOR CHARLES S. DENEEN, OF ILLINOIS.

The Chairman. I now take pleasure in introducing to you, gentlemen of the conference, Governor Deneen, of Illinois.

Governor Deneen. These internal waterways of the United States which rise in the Mississippi Valley and find their outlet in the Atlantic Ocean or the Gulf of Mexico were, in their natural state as known to the white settlers of the country, divided near the point where Chicago now stands by "one-half a league of prairie." So wrote Joliet, in 1764, after exploring "the Chicago divide." The importance of this fact did not escape the attention of this early discoverer, for in describing a water route from the Great Lakes to the Gulf of Mexico, he continues:

> The route to be taken is this: The bark should be built on Lake Erie, which is near Lake Ontario, and it could easily pass from Lake Erie to Lake Huron, from which it would enter the Lake of Illinois [Michigan]. At the extremity of this lake would be the cut or canal of which I have spoken, to have a passage to the St. Louis [Des Plaines] River, which empties into the Mississippi. The bark, having entered this river, could easily sail to the Gulf of Mexico.

The observations of this early explorer, so natural to one who had penetrated into the heart of the continent by means of its Great Lakes and water courses, were the forerunners of the many others which are to be found embodied in our state papers, beginning with the ordinance of 1787 for the government of the Northwest Territory, which provided for the free navigation of the waters leading into the Mississippi and St. Lawrence, down to the latest report which the present internal-improvement commission of Illinois submitted to the general assembly of that State on April 10, 1907, which demonstrates the feasibility of uniting the waters of those two great systems.

Various causes, however, have intervened from time to time to delay the removal of the slight barrier thus dividing the eastward and southward flowing waters of the interior of the American continent. Lack of means and the transfer from the rivers to the railroads of the bulk of the great freight and passenger traffic of the country have been among the chief causes to contribute to this result.

With the enormous and rapid development of our railroad transportation systems, the navigation of our internal waterways has declined to such an extent that what has been accomplished along the line of waterway construction and improvement has, until recently, been rather of local than of general advantage and significance. An illustration of this is found in the early canal projects which were undertaken in Illinois.

Of these, the first to be constructed was the Illinois and Michigan Canal, extending from Lake Michigan at Chicago to the Illinois River at La Salle, a distance of 97½ miles. This canal was constructed under the authority of a statute of the United States enacted in 1822, followed by a grant of land made in 1827 by the Federal Government "in aid of a waterway from Lake Michigan to the navigable waters of the Mississippi River." Construction work was begun in 1836. Its depth is 6 feet, with a width at the surface of 60 feet and at the bottom varying from 36 to 48 feet. Its locks are 110 feet long, 18 feet wide, and 6 feet deep. Its limited dimensions, together with prolonged low-water periods in the Illinois River, have prevented the canal from developing its full utility. But its incidental effect upon freight rates in its vicinity have been so pronounced that in 1885 Canal Commissioner Brainerd estimated that it had saved the people of the State within reach of its service not less than $180,000,000 in freight charges.

In 1837 the general assembly of Illinois passed "an act to establish and maintain a general system of internal improvements," under which liberal appropriations were voted for the development of river and railway transportation facilities, but, owing to the financial stringency of 1837, no substantial results were accomplished, and in 1840 the act was repealed.

From that time forward numerous projects for the improvement of local navigation in Illinois streams were formulated and surveys made, but no important work was accomplished until the construction of the Illinois and Mississippi, or Hennepin, Canal was entered upon in 1890 for the establishment of waterway communication between the Mississippi River at Davenport, Iowa, and the Illinois River at Hennepin; also affording, through the Chicago Drainage and Ship Canal, whose construction was begun two years later and of which I shall speak hereafter, communication with the Great Lakes. By the natural water route along the Mississippi and Illinois Rivers the distance from Davenport, Iowa, to Chicago is 610 miles. That distance has been reduced by the construction of this canal to 190 miles, a saving of 420 miles between Chicago and all points on the Mississippi River above Davenport, Iowa. This canal has a depth of 7 feet, is 80 feet wide, and has locks of 170 by 35 feet. It is available for boats 140 feet long and of 600 to 800 tons burden.

In more recent waterway construction, however, our State has shared in the awakening to the larger possibilities of waterway development with which the country has entered upon the study of our internal waterways, with a view to their development, extension, and unification upon the broadest scale. This has been evidenced by the interest which the citizens of Illinois have taken in waterway questions in which our State has only a joint interest with others. The Illinois general assembly in February of this year appropriated $10,000 for the investigation of the Mississippi River between Cairo and St. Louis, an appropriation made solely with a view to procuring information which would enable the State to conform its domestic waterway developments to any proposed developments of the main channel of the Mississippi.

The new attitude which we have assumed toward the problem of waterway development has been largely forced upon us by the necessities of our growing internal commerce. The railroads, which for a time provided an adequate, and later a more or less adequate means of transportation for our domestic produce, have now clearly become incapable of meeting demands. In this situation we find ourselves confronted, according to the view of those best qualified to pass upon such matters, with the alternative of a practical duplication of our present railway systems or the transfer to our rivers and lakes of a larger part of the transportation work of the country.

Both the experience of other countries and our own matchless natural facilities have turned public attention toward the waterways in seeking a solution of this problem. Not only is the Federal Government entering upon the task of formulating a general plan of waterway construction which shall treat the work of developing our entire internal waterways system in a comprehensive and systematic way, having regard to the possibilities of intercommunication between and, so far as possible, the unification of its interdependent parts; but the States and localities contiguous to our internal waterways, and which will receive special benefit from their development, are now considering their local projects with due reference to their relation to the general plan.

I think that no feature of waterway development is of greater importance. Other countries, notably France, have had the experience of building independently constructed parts of a general water transportation system upon different scales of magnitude, only to discover with the completion of the system the enormously increased difficulties thereby occasioned and to be forced to correct the mistake by a reconstruction of the work upon a uniform scale. Fortunately for us, we have been forewarned of this danger, and at the inception of a general waterway policy for the country are "getting together" for the consideration of the best methods of carrying out the work with the largest possible local and general advantages.

Great advancement was made in this important direction through the tour of inspection made by President Roosevelt along the course of the Mississippi River from Keokuk, Iowa, to Memphis, Tenn., and the convention at the latter city which brought to a close the President's visit. That gathering brought together the advocates of nearly every local project and those whose interests lay in the development of the internal waterways system as a whole. The mutuality of benefits was there made manifest and discussed and some advancement was made in the recognition of the necessary cooperation between the States and the Federal Government and of the principle that States and localities should contribute to the general program in some proportion to their exceptional benefits.

As I have said, the citizens of Illinois have recognized the larger meanings of local developments. They are also fully aware of the special benefits to be conferred upon their own State through the general development of commercial waterways, and are now carrying forward local waterway work of the most extensive and expensive character upon a scale of magnitude commensurate with any probable future projects of national scope or benefit.

When the sanitary necessities of Chicago demanded the diversion of the sewage of the city from Lake Michigan and the project of constructing a drainage channel was entered upon it was stipulated in the act creating the sanitary district of Chicago, passed in 1889, that—

> when such channel shall be completed and the water turned therein to the amount of 300,000 cubic feet of water per minute, the same is hereby declared as a navigable stream, and whenever the General Government shall improve the Des Plaines and Illinois River for navigation, to connect with this channel, said General Government shall have full control over the same for navigation purposes, but not to interfere with its control for sanitary or drainage purposes.

The channel constructed under this act by the sanitary district of Chicago is the largest artificial waterway ever constructed by man. At a cost of $44,000,000, it has extended the navigable waters of Lake Michigan southward 36 miles to Lockport, establishing water communication between the Great Lakes and the Mississippi and the Gulf of Mexico.

This work has made the establishment of practical commercial navigation between the Mississippi River and the Lakes merely a question of the extension of this artificial channel and the deepening of portions of the Illinois River. For the prosecution of the former work the citizens of Illinois, at the general election held November 3 last, approved a constitutional amendment permitting the legislature to issue $20,000,000 in bonds. One of the most important questions, therefore, which will occupy the attention of the general assembly of Illinois at its forthcoming session will be that of the construction of an additional link in the waterway joining the Great Lakes and the Mississippi. There had been much discussion of this project, of course, prior to the submission to the people of the recently approved constitutional amendment. The internal improvement commission of Illinois, in its report to the general assembly, and in other publications, had called public attention to the possibilities of water-power development in connection with the proposed waterway construction. Its report to the general assembly has shown that between Lockport, the present terminus of the Chicago Sanitary District Channel, and Utica on the Illinois River, a distance of 61½ miles—the stretch of channel to be constructed with the proceeds of the $20,000,000 bond issue just authorized—there could be developed 130,000 electrical horsepower worth $25 per horsepower per annum, an amount capable of retiring the bonds in a period of seventeen years from the inception of the work and thereafter producing a perpetual annual revenue to the State of approximately $2,750,000.

This commission also, in conjunction with the state geological survey commission, is investigating, as an incident to waterway construction and stream development and correction, the resulting reclamation of lands in the Illinois Valley now subject to overflow.

The reclamation of submerged lands, in which the Illinois internal improvement commission will cooperate with the state geological survey commission and the United States Department of Agriculture, is one of the principal items of collateral benefit which are to flow from stream development for navigation purposes. Surveys have already been made by the geological survey commission of the overflow lands adjacent to the Kaskaskia, Big Muddy, and of portions of the Sangamon, Little Wabash, and Embarrass rivers. The submerged lands of the State susceptible of reclamation amount to nearly 5,000 square miles, an area greater than that of the State of Connecticut or the island of Porto Rico, and are, of course, among the richest alluvial lands of the State. It has been estimated that over $100,000,000 will be added to the land values of the State by the reclamation of submerged lands, and that in addition thereto certain portions of the improved streams will be rendered navigable.

In this direction work of a very important character has been entered upon in various Illinois River valleys by local associations formed for the purpose. The possibilities of valley organization for the development of local navigation water power and other collateral utilities are very great. An organization of the character mentioned has been formed in the Rock River Valley having for its ultimate object the development of the water power and other resources of the valley in conjunction with a waterway which shall traverse the valley from the Mississippi River at Rock Island and be eventually extended to Lake Winnebago, to Milwaukee on Lake Michigan, and to the Wisconsin River. The water power capable of development in this valley amounts to 100,000 electrical horsepower, to be developed in part by the aid of storage reservoirs. This power should be worth not less than $40,000,000 as a going concern and represent in industries and growth of population an increased wealth eight to ten times greater. The valley has an area of some 11,000 square miles, located in part in the State of Wisconsin, and its full development involves the cooperation of the people of the two States. Happily, the federal Constitution has provided for such cooperation after securing the consent of Congress and the passage of a federal enabling act.

Another valley which has been given preliminary investigation is the Fox River Valley, almost wholly within the State of Illinois, which has a watershed about one-fourth that of Rock River, capable of developing water power and other collateral utilities of proportionately the same value. I expect to see this movement for valley organization extend, as it should extend, until it comprehends the watersheds of our main streams, and thus through the detailed development of the valleys, in response to local motives, the main streams will themselves receive a large measure of improvement in the form of increased water supply and be furnished with commercial feeders through these tributary valleys. In this manner the policy of conservation and waterway development will be gradually extended by local and state effort, in cooperation with that of the United States, until it will affect every town site in valleys where a stream bed exists large enough to be adapted to waterway development.

The possible and proposed extensions of navigation along some of these streams bear close relation also to another phase of the work of the Geological Survey Commission, that of the development of the mineral resources of the State. The restoration or creation of navigable conditions in many of these streams will carry water transportation into some of the most extensive coal fields of Illinois. I mention this as an illustration of the widening circle of benefits which are incidental to the extension of our domestic waterways. It is not my intention to speak at length upon this subject. I may, however, advert to one other instance of the avidity with which local projects in our State are seeking to avail themselves of whatever advantages may be made to accrue to adjacent communities from the construction of the great commercial waterway from Chicago to St. Louis.

Through the city of East St. Louis, which lies on the eastern bank of the Mississippi River opposite St. Louis, a small stream called Cahokia Creek flows, carrying off the surface water from the adjacent low-lying flatlands. The sudden floods to which this creek is subject have proven a great inconvenience to the city, and plans have been devised for diverting the waters of the creek from their course through the town into an artificial channel 16 miles long, 300 feet wide, and 20 feet deep. This will carry the waters of Cahokia Creek around East St. Louis and discharge them into the Mississippi River 6 miles below the city.

The estimated cost of this work is $6,500,000, and for its prosecution a sanitary district has been formed embracing portions of the counties of Madison and St. Clair, comprising an area 27 miles long and from 1 to 7 miles in width. This sanitary district includes a large and populous manufacturing area and extensive railroad properties, and has an estimated value of $75,000,000. The district was created on September 22, 1908, and the election of trustees will occur on December 16 next. The work of surveying and construction has been placed in charge of engineers of national and international reputation. They are Gen. O. H. Ernst, of the United States Engineer Corps, who for many years had charge of the Mississippi River work between St. Louis and Cairo; Maj. B. H. Harrod, at the time of his appointment and now a member of the Panama Canal Commission, and Maj. D. B. Dabney, of Vicksburg, Miss., who is also in charge of the Vicksburg and Yazoo levee and drainage district.

From these experienced men none of the possibilities involved in the local situation was hidden, and one of the results confidently looked forward to by them and the citizens of East St. Louis is the connection of their surface water channel with the channel of the deep waterway, and the use of the former as a commercial water course. This result will be made possible in the event the plan of the United States Board of Engineers is carried into effect. It is recommended by that board that, instead of using the Mississippi River between Alton and St. Louis, a canal paralleling the river be dug. This will avoid the stretch of river at its intersection with the Missouri, whose cross current deposits an enormous quantity of material in the bed of the Mississippi, demanding constant dredging to maintain a navigable channel. Should this canal be dug, the city of East St. Louis proposes to connect its local channel therewith, giving the city a commercial waterway upon three sides, and furnishing extensive wharfage upon the water side to many of the large manufacturing plants of the city.

No doubt it was the existence of these and other collateral benefits in various localities which reconciled the people of Illinois to the expenditure of so large an amount of public money in waterway construction. In this connection it may be said that there are probably few, if any, localities upon which will fall the burden of waterway construction entirely unrelieved by collateral benefits. In almost every instance the question of waterway development is also a question of the acquisition of water power, of land reclamation, of fisheries improvement, of the betterment of health conditions, of the extension of industrial areas, and the utilization of other incidental benefits, frequently aggregating many times the direct outlay for waterway construction.

This feature of waterway development has received additional exemplification and emphasis of late through the conference held in the city of Washington upon the invitation of the President for the discussion of means for the conservation of our natural resources. The correlation of the different forms of conservation became manifest the moment that representatives of distant and extensive areas, having a great variety and apparent diversity of interests, undertook their joint discussion. The mutuality of interest and the immense possibilties of collateral benefit furnished one of the most hopeful aspects of the waterway question. Whatever the cost of it, the country must perforce, I believe, undertake the improvement and extension of our domestic waterways, and in this situation it is most reassuring and encouraging to find that the necessary initial expenditure will be largely repaid from sources incidental to the main undertaking, and that this will, in addition, provide, through the water power developed, a permanent revenue which may be advantageously devoted to the further extension, improvement, and maintenance of our waterways.

This is especially gratifying in view of the fact that the waterway, as such, will not be a revenue producer. It will be maintained at public expense as an open highway for the free and unrestricted use of the citizens of the country. When we consider what an enormous traffic has been developed upon our lakes we may appreciate the effect of an extension of these magnificent bodies of water through the construction and improvement of navigable channels communicating with them at one terminus and with the ocean at the other, and traversing the rich mining, agricultural, and manufacturing regions of the interior. That the area available for manufacturing enterprises will be thus greatly extended is evident from what has already occurred where water navigation has been naturally available. Many of these enterprises depend for their prosperity upon the cheapness of transportation facilities and these facilties the improvement of our waterways will furnish in abundance.

In this connection I may say that I do not for a moment believe that the development of waterway communication offers the slightest menace to the future prosperity of our railroads. On the contrary, I am of the opinion— now held, I believe, by those who are best informed upon the subject—that in the present congested state of our railroad transportation systems the transfer of a great deal of the heavier, coarser, and slow-moving freight would be a distinct advantage. There is, I believe, a natural and marked distinction between the transportation uses which can be best subserved by the swift-moving railroad service and those which are fully met by the slower but cheaper water transportation.

Statistics show that, in round numbers, one-third of the freight moved by rail is worth less than $1 per ton at the point of production; another one-third exceeds in value $5 per ton; and one-third ranges between $1 and $5 per ton. It is apparent from any study of the cost of transportation of primary products that if these could be handled more cheaply than now, the output of high-class freight would be greatly increased and the railroads would receive a double benefit. They would be relieved of low-grade freight, which they now find it necessary to move in order to maintain the output of high-class freight, and the production of high-class products, which furnish the most profitable class of freight traffic would be greatly stimulated. It will be found further that there are vast resources in our domain which will not bear railway transportation and for which waterways are a necessity if they are to be developed.

It is not my intention, however, to dwell upon particular phases of this broad subject. These will be discussed doubtless by those more familiar with their details than I profess to be. In what I have had to say I have attempted to deal only with some of the general aspects of the waterway question as they have presented themselves to me. It seems to me that in any policy to be adopted for the conservation of our natural resources, the preservation of our navigable waterways for the public benefit must occupy a foremost place, and that the discussion of this very practical and pressing question is of the utmost importance at this time.

GOVERNOR N. B. BROWARD, OF FLORIDA.

The CHAIRMAN. I will call on Governor Broward, of Florida, to address us briefly on this question.

Governor BROWARD. Mr. Chairman, ladies and fellow-citizens from every portion of the country, it is very difficult for one to undertake to speak after others have preceded him, not one or two, but by the dozen, who have carefully studied the problem that we are attempting to solve, and for one to come at this late hour and undertake to talk about something that every one present is perhaps better informed about than he, is to undertake the impossible. It is always poor policy to undertake to make excuses. Persons are not interested in excuses, but I will make the excuse that I have been exceedingly busy since I have been here, and have not had the privilege of listening to those who have already spoken, and who have given this matter careful consideration. Therefore, I approach the subject as a boy might approach the side of the ocean when he is commanded to cross it without boat or oars.

It is fortunate for us that Mr. Pinchot and his splendid coworkers have done so much to place before us the facts that provide us with so much food for thought. Those who first came into this country thought that the forests were exhaustless, that the mines were inexhaustible, and it seems that even up to now there are many of our people who believe that we are on a wild-goose chase, that we are afraid of something that there is no real reason to be afraid of, and that to talk about conserving the forests, or the water supply, or the coal supply, or the iron supply, and all of that kind of thing, is folly.

But if one will only travel over this broad land from one ocean to the other, from the Lakes to the Gulf, he will soon be impressed with the fact that the forests are disappearing rapidly and that those who own them say they are receiving but a very small compensation for the value of the property they are parting with.

In the State of Florida, covered as it once was with tall yellow pine, so that a single acre of land would provide to the miller, perhaps, 10,000 feet of lumber, it has been cut off very largely over the whole State, so far as that State is concerned. The turpentine man has come in and is boxing the trees down to such a size that sometimes cutting a box on one side will cause the tree to fall in a moderate wind. Sometimes fire gets in and destroys many more, and this, with turpentine selling for 35 cents a gallon, which is no price at all for the value of turpentine, even not taking into consideration the great value of the trees to the State in which they are and to the owner of the trees.

We look around the headwaters of our streams and we see the hillsides along the rivulets and branches being denuded of the timber and even the vegetation disappearing in many instances. We can see that the time is near by when that section of the country must suffer from first a drought and then a flood, as there is no foliage to retain the moisture in the land, and therefore it is just as though you would throw a cup of water in a tin basin that will not absorb or retain moisture and then tip it so it will run out; you would have a drought almost as quickly as you would a flood by throwing the water down and letting it run to the sea, unused in many instances, and not retained long enough to be of much use to anyone.

The fact that these gentlemen have gone out into this country and have made these careful investigations, have estimated the value of our water, if used as power, and the many uses to which both the power and the water can be put on its way to the sea, is not only a great credit to them, but will become a great blessing to the people of this country. If the people will act in concert and take advantage of the situation while they may, great good will result. To preserve the forests is necessary. Reforestation is necessary. It matters not whether it comes at a large or small cost, we must provide for the years to come; the not far distant years, but years almost in sight. At the present rate of cutting in the State of Florida, the vast timber areas that I see so graphically described by some man in Michigan as existing in Florida will disappear within twenty years, and twenty years is a short time. I am 52 years old now, and I expect to be here that long. In many instances we cut the timber down, oak scrubs spring up and grow in place of the trees that are gone—not trees with great leaves falling from them to retain the moisture and to fertilize the soil, but a species of bush that does not retain much moisture and does not fertilize the soil by its falling leaves. As a result, the land grows poorer instead of richer.

In the next place, our State has been burned over every year by forest fires. The man who has cattle sets fire to the weeds and grass as early as February and burns the old grass off with a view of having a "new burn," as he calls it, or new grass for his stock. The young pines are burned off that are only a year old, and you can find some sections of the State entirely denuded now. In some sections where by good fortune it has not been burned over regularly you will notice saplings two years old as tall as this room is high, showing how quickly we could reproduce our forests if we would only stop the waste.

I have twice recommended to the legislature that action be taken to protect our forests; that fire districts be laid off and keepers be put upon them to protect the forests from fires, with a view to reproduction of our forests, but so far it seems that the doctrine is that everyone will do all he can to make the dollar in sight and never think of the waste that is taking place. In many instances the man can not afford to consider that. He owes the bank, and the bank has loaned him somebody else's money, and he must go on, though he knows that it is waste, and cut his timber.

That some general plan should be entered upon, understood by the representatives in every State, and some uniform action be taken, goes without saying. It is well for us to be here to consider these things and see what can be wrought out of such work as this. There is not a State in the Union, unless it be out in the Far West, but in my section of the country especially, where the country is not getting dryer all the time, and particularly is that applicable to Florida. Not only do we vote our State dry, but less water is retained there as well. We are getting dryer all the time. It is true there is one portion of our State that has more water than it ought to have. You will notice by the reports that on the east coast of Florida, toward the southern extremity of the State, known as the Everglades, 81.66 inches of rainfall has come to us this year, up to the 12th day of November, beginning at the 1st day of January. I have no doubt we will have fully 8 feet of rainfall by the end of the year. In spite of that the territory is gradually becoming dryer in the upper portions of the State. In many instances the farmers are irrigating their farms. Bankers at Gainesville do not hesitate to lend money to the farmer who will irrigate his crop, and will not lend money to the farmer who does not irrigate his crop, unless he has property other than the crop expected to be produced by the money loaned, which shows the importance of irrigation in one portion of the State of Florida. In the other portion of the State we have now already entered upon a plan to dig 250 miles of canal through what is know as the Florida Everglades, with a view of lowering the level of the water in the land so it may become cultivatable, and with a view also of offering to these people in this country an opportunity for planting sugar cane. With an area larger than Connecticut, Rhode Island, and Delaware combined, almost as level as this floor, covered with a few inches of water most of the year, lying idle with scarcely a tree upon it and nothing but coarse grass, unless the water is reduced from the surface and the land thereby be made sufficiently dry to cultivate, it will never be of any value to us or to the State. It is land which, when drained as we hope to drain it, is as rich as any other in the world. There are a million acres of that land that would produce more than the 30,000,000 acres of other ground in the State, so far as valuable crops are concerned.

We have entered upon this work of drainage in the last four years. Though the land was patented to the State nearly sixty years ago, to aid the State in draining and reclaiming this territory, nothing effective was done with it until recently. In searching the records of the Senate you will find that Senator Breeze, of Illinois, recommended the passage of a similar bill to the one that was passed without amendment, granting to that State all the land lying south of the north end of Lake Okeechobee and between the Gulf of Mexico and the Atlantic Ocean, on condition that the State should drain and reclaim the land and apply the residue to purposes of education. So long ago as fifty-five years, the state legislature created trustees to carry on this work, but the only effective work has been begun within the past four years. Political bodies move slowly. It is necessary that the people shall get behind their representatives and impress them with the fact that they propose to have their work done. All kinds of obstacles are found in the way of an attempt to do any work of this character. As the President suggested the other evening, you will find many difficulties to overcome before you conclude the solving of the problems that are considered here.

We want men with intelligent minds and with strong will. We want to offer one prayer for the people of this nation, if we offer no other, and that is that they will trade off spareribs for more backbone.

We should conclude in the outset that God made this country for the people who are in the country, and not the people for the country. We should appreciate another fact, that this is our country, all of it, and that all of the highways should be used for the people, for the benefit of the commerce of the people, and that the people should not be used simply as a means by which the owners of the highways make money for themselves.

Sometimes when I look this problem duly in the face I see why the bravest of us dodge the problems, and I have really walked around some of the problems until some one discovered me and I had to face them. It is necessary, I believe, that all of us get discovered sooner or later. We must enter upon some plan with reference to these problems. I heard the governor of Louisiana make a speech this morning here. He suggested a plan that he thought feasible. I will not venture a plan upon this occasion, but will make suggestions that we may consider.

I believe our State should retain as much of its own public domain as possible. A small portion of our once proud public domain is left to each of the States. Though Florida was granted by the National Government all of the swamp and overflowed lands within it, and there has been patented to it 20,150,000 acres, yet 17,000,000 acres of that land have been given to railroad and canal companies, so that we now have left only 2,260,000 acres. Every contract made with a company to build a railroad, every grant of land wound up with this language, "and drainage," providing that they should build a railroad on certain specifications, and conclude with the provision, "and drainage," because the legislature thought they had to say something about draining the lands, or they had not a right to give it away, as the land act of Congress expressly required that the land or its proceeds be used exclusively for that purpose. When the statutes were compiled there was included therein this language: "Provided that the lands herein granted shall remain subject to the control, management, and sale of the trustees of the internal-improvement fund for the purpose of said trust under the said act," which trustees were created by the legislature to carry out the contract with the Federal Government to drain the lands. As soon as they would undertake to consider a straight course, then one proposition and another would be offered. Contracts were entered into, but out of all the contracts to drain land less than 20,000 acres were ever truly drained. Now we have entered upon a plan of really reclaiming by drainage the 2,200,000 acres that the State still owns, and about 2,000,000 acres of adjacent land of the same character.

I do not know what the other States have done with their lands. I am afraid that if stock was taken of the public land in those States they would find that the men who were more ambitious than others and who had some special interest to conserve got more than their share. A too liberal policy prevailed in our State; no dishonesty, but they simply got to giving the land away, and it seems we could not stop it. When I was elected governor I declared we would not deed away more land, and proposed to retain what we had and reclaim it according to the former contract with the nation, when great opposition sprang up. Twelve different lawsuits were brought in the federal courts and some in the state courts, and some of them still exist, though we have won at nearly every stage of the fight. Therefore, my countrymen, you can rest assured now that there are obstacles in your road. There are many difficulties to overcome. But, I say to you, overcome them and do not protect the interests of a few selfish people who are endeavoring to obtain the advantages for themselves regardless of the interests of all the other people.

While I am suggesting these difficulties and obstacles which you will have to overcome, I do not want to get in the position of the good old minister, to whom I listened on one occasion. He invited everyone to join his church. He wanted every sinner to come into the fold, sign the roll, and become a member of his church. He impressed the audience with this thought, "It is hard to be a Christian; it takes a man or a woman to be a Christian." And I looked at the little children in the audience and the young people who were about to get married, and wondered what would become of them. He kept on until a Christian looked as heavily laden as does Atlas with the world on his shoulders, and then invited every person to walk up and sign the roll loaded down in that way. The result was that nobody walked up. I do not want you to get too heavily laden, but we must all realize at all times that if we are to succeed we must succeed by individual effort. Everyone should act along some well-defined lines. Write letters, talk to your neighbors, talk to your governor, to your member of legislature, petition Congress. The reason we complain so much of our Representatives in Congress not doing so well for the public generally, but doing well, as we claim, for the special interests is because we do not stand by them. If they stand up and fight for us, we do not stand up and fight for them. The result is they must take the middle course and become very conservative, lest they be left at home entirely and not be permitted to come back to Washington again. We are men and women.

We are human beings, and we are controlled largely by the same influences. The firmest body will turn out of its way any other body of less weight. We are bound as we go along to yield to forces superior to our own, but if all the people will think together, and if the great majority of the people will act together, every other weight or influence must give up to them. We must think. We must be proud of our Representatives. Stand behind them, and if there is one of whom we can not be proud, keep him at home, guard him carefully, and do not let him come up here to harm himself or to harm us. Agitation is necessary to succeed in carrying out any great policy. Cooperation is necessary, and to become acquainted is necessary. You know a great many of our people in the South and in the North and in the West are afraid that we might get too close together and that the Federal Government might get too great a hold upon the hearts and minds of the people of the different sections. There are those who are afraid that this safeguard will be knocked down, and as a result the sovereignty of our States disappear, and all that kind of thing. In all probability there is some danger along that line, but it is not imminent; it is not close by. So far as I am concerned, coming from the far southern portion of this country, I want to say this to you: All of this country looks good to me, and I propose to have any piece of it that I set out to get. I do not know but what I would have it all if I could. In a jocular sense, we have tried one experiment and it did not work. The folks up this way loved us so much they would not let us go; they held us back. I do not think there is anybody down our way who wants to break loose any more, but we propose to come up here and take what you have. We are willing you should come down and take whatever you can find down our way that is not nailed down.

However, while we may speak of sectional lines, let me say to you that there are none. The fellow who talks about sectional lines here, there, or yonder, is a man who has not traveled very far. The more we get about our country and the more we understand each other, the more we think of each other and the less we think of ourselves. It has been said, "If a man would be joyous, look without; if he would be miserable, look within."

Sometime ago I was in the State of Nebraska, and I was impressed with this thing, which shows that when our people think, great good will come from their thinking. The governor and his wife took me out to the asylum first, and we took lunch there. From there we went to the penitentiary and took dinner. After getting inside of the walls of the penitentiary, I said to the warden, "What is your death rate here?" He said, "I have only been here four years. We have had an average population of 408 for the four years, and the only death we ever had during that time was caused by hanging. We hung one man." I said, "Tell me the secret." He took me out to where the prisoners were required to work, thence to the bathrooms, thence to where they slept and lived. The sanitation was perfect. Sanitary conditions could not have been better. The rules were enforced rigidly and good health resulted. No person died in the four years of any disease. The only man who died came to his death from hanging, and of course he could not help that.

Now, my countrymen, this is an indication. This points toward what can be accomplished for the good of humanity, for the health of humanity, and if we will only think and act in the same way, we will have no difficulty in conserving our products. There was an example of the conservation of human life. We can in some similar way conserve our waters. The coal and iron and all of the other riches that bless this country, can be conserved in some way; but it will require careful thinking, careful acting, and when we have careful thought and careful action, the battle will have been won, and we will not only be benefited by it, but our names will be revered by those who come after us; and as I said yesterday evening, of Mr. Pinchot and Doctor McGee and Senator Newlands and all the others who were appointed and who went out to take up this great work of considering the conservation of these natural resources and the purification of the waters and all that kind of thing, their names will be preserved on parchment and hung upon the walls throughout this land, and they will be appreciated throughout all the years to come as persons who looked forward, who thought not only for themselves, but thought that those who were to come after them were entitled to some of the good things of the earth, as well as those of us who are living in this day and age.

When we have each done his full duty in this life, each one will leave it feeling that this work was not half done; that he had only accomplished a small portion of what he would like to have accomplished. I saw the other day a man in declining years and in declining health. When some one asked him how he had enjoyed life, what he had to say, he made this declaration:

> I feel that I have done my best. I did not start early enough, it is true, but for the last twenty years I have worked every hour that I could. I have done well every piece of work that it was my duty to do and that I undertook to do, and I can look up at the planets in their course and say I, too, have done the work that was allotted to me, and I challenge you to do more.

I say this to every person present, that it is the duty of all of us, if we would enjoy that consciousness which a good citizen ought to enjoy, to feel as he goes toward the grave, "I have done all that was in my power, not only for the glory of the God who created me, but for the joy of the people, of my neighbors, for the sake of Him who blessed the world and with whom I expect to dwell throughout all eternity."

I will not keep you here any longer making a rambling speech. My heart is with you. I will do everything in my power in the section of the country in which I live to preserve the forests, to have the water courses properly utilized, to insure to the people of the country the completest use of these natural riches that were put within their reach by the Creator himself; and whether successful or not I shall go out of the fight proud of the opportunity, proud of the part that I took in it, and having no regret except that I had not accomplished more.

I thank you for your kind attention.

GOVERNOR ROLLIN S. WOODRUFF, OF CONNECTICUT.

The Chairman. I now take pleasure in presenting to you Governor Woodruff, of Connecticut, and I know we shall all be glad to hear the message he has for us.

Governor Woodruff. Mr. Chairman, ladies and gentlemen, I have enjoyed all of the exercises of the past two days exceedingly from the very fact that my name has not been on any of the programs, and I have not been obliged to think that I was going to be called upon to say anything. I am, however, glad to appear before you to represent our little State of Connecticut. We are a small State. We are a manufacturing State. We have no mineral resources. We have no waterways that need developing. We have, however, Long Island Sound, which helps our manufacturers to get raw material at moderately low prices. We are simply a producing State. We have the reputation of manufacturing some things, but that reputation is not well founded. We have been accused of manufacturing wooden nutmegs, but I assure you, gentlemen, that is not true. We have, however, in the past produced many things and a great many things that have been produced for the first time.

We produced a constitution, the first written constitution, and the United States Government copied after it. We have produced a great many men who have been prominent in this country. We are proud to say that we have a living example right here of our own product—Mr. Pinchot.

We concur in everything that has been brought out here in all these great questions which are being discussed. There is no State which will receive greater benefit if these projects are carried through than will our little State of Connecticut. We need raw material because we are producers, we are manufacturers, and none of you, no matter from where you came, can go into any hardware store or agricultural-implement establishment where you will not find some of the products of our Connecticut.

We stand ready with the other States to take any action that may be necessary to bring about all of these good things which you are considering. It is simply a question of education, gentlemen. You can not expect to wake up to-day, walk up to the National Government and present your case, and expect that they will open the strong boxes of the Treasury and hand over to you the necessary funds to carry out these projects. The people must be educated. They must be so thoroughly educated in all these questions that these Representatives in Congress will absolutely be forced to give you what you want in a reasonable way. All this takes time. Mr. Pinchot, in his forestry work, has done a remarkable work. It is only a few years that he has been at it, and he is responsible for bringing out all that has been done in the way of forestry.

We have no forests in Connecticut. We have a few wood lots. Our State appropriates a very small sum to our state forester to-day to enable him to do some things, and he has done them in a small way, mostly in an experimental way, but he has shown what can be done.

Within the last two weeks our New England governors have come together and considered certain common laws which were for the benefit of all of our New England States. We had a conference week before last similar to this, in which the question of forestry, the question of the cultivation of the lobster, the question of good roads, and the question of a uniform automobile law were considered. We propose to have in New England a uniform automobile law, so that when you gentlemen wheel into New England you will know that the law throughout New England is the same. I believe that the States can come together in this way and accomplish a great deal. It is right along the same lines that we are considering here, and a great deal can be brought out of it. I do not know that I have anything more to offer at this time, Mr. Chairman. I am highly pleased to have been called upon to represent our State at such a meeting as this.

I thank you very much, gentlemen.

Mr. PAGE, of Virginia. Mr. Chairman, I rise to a question of personal privilege. I am perfectly willing to accord to the great State of Connecticut all the wonderful work she has done, and I am willing to say in behalf of the country that in the production of Mr. Pinchot she has done probably her greatest work, so far as that may be concerned. But I must say, in behalf of Virginia, that I do not admit that Connecticut was the author of the first Constitution of this country.

EX-GOVERNOR SAMUEL R. VAN SANT, OF MINNESOTA.

The CHAIRMAN. I will now call upon Governor Van Sant, of Minnesota, for a few remarks. I take pleasure, gentlemen, in presenting to you Governor Van Sant, of Minnesota.

Ex-Governor VAN SANT. Mr. Chairman and gentlemen, it has seemed to me since I came to Washington that every person I met was either an officeholder, an ex-officeholder, or willing to be an officeholder. I was introduced as governor—I can not for a moment sail under false colors. Minnesota can have only one governor, Governor Johnson. So you see I am not a distinguished statesman, but an extinguished one—only an ex-governor, if you please.

For more than thirty years I have been actively interested in the waterways of our country. I am a steamboat man, and had thought until I came to this meeting that I was the only steamboat captain who was ever the governor of a State, but I have since learned that the governor of Florida was also a master of steam vessels, so I have to divide that honor with him.

I have just come from the River and Harbor Congress. It is a great gathering of splendid, determined American citizens. I predict a speedy improvement of our waterways. Those men mean business, and in time will get what they have so long contended for.

There has been such an aroused public sentiment that practically every commercial body, chamber of commerce, board of trade throughout the length and breadth of the land favors this great movement; and I doubt if any candidate for Congress, in either party, in any State of the Union, would have the temerity to stand up before election and say to the voters in his district that he was opposed to the improvement of the waterways of our country.

In my judgment, when we have a perfected and completed system of waterways, it will do more to solve the rate problem—in fact, the whole vexed transportation question—than all the laws that we may be able to put upon our statute books.

I am glad to look into the faces of my coworkers in their efforts to conserve our forests, for I am also a delegate here. I promise you that so far as my ability and my strength go I am with you heart and hand, and will aid you in every measure that will help to preserve our forests; for in doing this I feel that we are advancing the interests of our waterways, for forests are essential if we are to have a sufficient water supply.

Yes, I will join hands with you and do all that I can; but we must remember that if we want anything we must not only ask but fight for it. This is a fighting age. Yes, we must not only ask Congress for aid, but we must fight, and fight hard. This is a representative government, and we send men to Congress to represent our views, and if we do our whole duty and make our wants known the Members of Congress will be only too glad to carry out our wishes. I think I know what I am talking about. No one has his ear to the ground and keeps it there longer than the officeholder, and no one is quicker to discern public sentiment than he, and to trim his sails accordingly.

I am not a pessimist; I am an optimist. I have no fear of the result. When I read the history of my country, I learn that we have met and overcome every obstacle in the past, and I am sure we will meet the difficulties which confront us now, and master them, too.

It is very gratifying to be here for another reason. It is a pleasure to meet the delegates from Florida, Georgia, and Louisiana, and from other portions of the South. We are united now for a common purpose and have no North, no South. I am glad indeed to meet so many ex-Confederates. The war is over and if these ex-Confederates will fight as hard to preserve our forests as they fought when I was in the Union Army and pitted against them, I am sure we will win, especially as we are all fighting for the same cause. United we can get anything we want.

Yes, the war is over, and I am glad to say in this presence that the warmest greetings and heartiest handshake that an old soldier gets is when he goes south and meets an old grizzled Confederate veteran. With the old soldiers on both sides there are no longer any animosities. The asperities of that great struggle have passed away. So I say it is a great pleasure to see so many public-spirited men from the Southland, who join with us in the effort to bring blessings to millions yet unborn.

Other gentlemen have spoken gloriously of their States, but it is not necessary for me to tell you of the glories of Minnesota. Governor Johnson has undoubtedly done that, and in the best possible terms. I can not, however, resist the opportunity to say a word about the North Star State. It is most fortunately situated in the center of the North American continent and midway between the Atlantic and Pacific and the farthest point toward the setting sun reached by tidewater navigation. It has two great waterways to the ocean; one via the Mississippi River, the other from Duluth via the great chain of lakes, and still another, if ever made necessary by a greatly extended commercial trade, via the Red River of the North and Hudson Bay. We raise the wheat to feed the world, have the largest mills in the world to grind it into the best flour ever made. We have iron ore enough to supply the wants of mankind for a century to come. Our forests for half a century have enriched our people, and have supplied surrounding people with lumber to build their happy homes. We have ten thousand beautiful lakes, and from this fact Minnesota received her name, the land of sky-tinted water. We also have numerous rivers, and our lakes and rivers teeming with fish and our forests alive with game make Minnesota the paradise of the sportsman. We have a vast area, the State being larger than all New England, New Jersey, and Delaware, and have more square miles than England and Ireland combined. Our climate is unsurpassed. The afflicted people of all States come to Minnesota to breathe her exhilarating air and to renew their youth. Yea, Minnesota ozone is famous the world over. A story will illustrate: A man from Florida, Georgia, or some other State, was very near death's door. His physician told him he could not live unless he changed climate and suggested Minnesota as the best place to go. He followed the advice, and after remaining in our State a few weeks he wrote back to his friends that he was getting along finely and that he felt twenty years younger. In due course of time his improvement was so great he wrote that he felt thirty years younger, and still later that he felt forty years younger. The next they heard from him, he had died with cholera infantum.

These conditions, however, do not constitute a State. Better, and above all, we have 2,000,000 happy, contented, and prosperous people, and these are Minnesota's greatest asset. But I must not tell you all the good things about our great Commonwealth; I fear I would do you a great wrong, for you might be induced to leave your present abodes and move bag and baggage to the great Empire State of the West.

GOVERNOR MARTIN F. ANSEL, OF SOUTH CAROLINA.

The CHAIRMAN. I am going to call upon Governor Ansel, of South Carolina, to give us a short address on this subject. I know we shall all be glad to hear from him about this matter.

Governor ANSEL. Mr. Chairman, ladies, and gentlemen, I have had one chance at this audience, I do not know why I should be called upon again this afternoon unless it is for the reason that I am a water man, interested in salt water, interested in fresh water, and am on the water wagon. You all know what the governor of North Carolina said to the governor of South Carolina. The last message that I have received from my distinguished friend, Governor Glenn, is that we want water, water, more water.

I represent in this body primarily the State of South Carolina, but also the whole United States. We are here to devise ways and means for the best interests of every State and of each State and of all the States. As you know, in South Carolina we have on one side the Atlantic Ocean. Therefore we are interested and greatly interested in navigation. We have in the other portion of the State the mountains, where they do not make sunshine, but sometimes they do make a little moonshine. We have fresh water there and we are beginning to take measures at this very time to utilize this great commercial asset that has been going to waste for years and years, and we are churning our waters from their very source until they get nearly to the Atlantic Ocean, and then we make ice out of them. One hundred and seventy-five thousand horsepower of that water is utilized at this very day for the purpose of making electric power, and we have 375,000 horsepower of water still to be utilized and to be used. That is in the nonnavigable streams of our State. Are we not interested in water?

We are interested in forests as well, because the sources of many of our rivers are in our mountainous country, where the trees are being cut down. I do not know when I have felt as badly as I did last summer a year ago, in looking at one of the mountain sides that I used to see covered with forests when a boy, large and small trees, and I asked, "What is the matter with that mountain side?" It was bare. I was told that a little sawmill had been put up there, and instead of having that loam soil that we have upon our mountain sides, it was going down into the creeks and into the rivers and into the sea, causing this great Government to have to spend money in dredging the navigable streams of our country, in order that the ships may float and carry the produce that is raised in this great country of ours.

I just wanted to say a few words by way of exhortation, but fear I might do as I have often heard done—spoil a good sermon by a very poor exhortation. I want to say that I am with you in this great work of preserving all of these bounties that have been so largely bestowed upon us, preserving them for our posterity—the waters, the forests, the lands, the minerals, which are the great riches of this country. Whether they be used in the next century or the two centuries or the next three centuries, let us preserve them for our posterity, in order that they may rise up in later years and call us blessed.

REPORT OF COMMITTEE ON RESOLUTIONS.

The CHAIRMAN. Gentlemen, the hour has arrived for the special order of business, and we must proceed to that business. It is a matter of very sincere regret to me that our time is so short, as I know it is a matter of regret to all of you. Possibly there may be a chance that some of the gentlemen who certainly ought to be heard may have an opportunity after we consider the report of the committee on resolutions.

I will ask Governor Pardee to present now the report of the committee on resolutions.

Ex-Governor PARDEE. Mr. Chairman and gentlemen, your committee on resolutions has had two or three meetings, and the opinion prevailing among the members of the committee was that the prime object of this meeting was for the purpose of either indorsing or refusing to indorse the report of the National Conservation Commission, which was appointed by the President, and has been holding its meetings during the last week or ten days here in Washington. Various resolutions on other matters specific in their nature were presented to the committee; some of them have been withdrawn by the gentlemen who introduced them, others have been considered of such specific importance by the committee on resolutions that they resolved to refer them to a committee which is called for in a resolution here to be presented, and others will be presented by us at this time. As I say, the report of the committee on resolutions embodies primarily the indorsement of the report of the National Conservation Commission, which will be presented to the President. The report of the committee on resolutions reads as follows:

This joint conservation conference in session assembled in the city of Washington on this 10th day of December, in the year 1908, representing the several States and Territories of the United States through governors of States, state conservation commissions, delegates, and representatives of state and national organizations dealing with natural resources, does hereby resolve and declare:

Having heard the report of the National Conservation Commission read, and having fully deliberated thereon, we hereby indorse the said report as a wise,

just, and patriotic statement of the resources of the nation, of the thoughtless and profligate manner in which some of these resources have been and are being wasted, and of the urgent need for their conservation in the interests of this and future generations, to the end that the prosperity and perpetuity of the nation may be assured.

We especially approve of the principle of cooperation among the States and between these and the Federal Government laid down in that report and in the earlier report of the Inland Waterways Commission, and urge both state and federal legislatures to enact such laws as may be necessary to extend and apply such cooperation in all matters pertaining to the use and conservation of our resources.

We especially commend and urge the adoption of the policy of separate disposal of the surface rights, timber rights, and mineral rights on the remaining public lands of the United States; and we approve the disposal of mineral rights by lease only, and the disposal of timber rights only under conditions insuring proper cutting and logging, with a view to the protection of growing timber and the watersheds and headwaters of streams used for navigation and other interstate purposes.

We also especially approve and indorse the proposition that all the uses of the waters and all portions of each waterway should be treated as interrelated; and we emphatically urge prompt and effective legislation providing for the immediate and proper development of the waterways of the country for navigation, water supply, and other interstate uses, preferably by direct federal appropriations; otherwise by the issue of bonds.

Approving those portions of the report pointing out the need for continued investigation and more extended scientific research, we also urge that this policy of gaining more definite and specific knowledge relating to our resources be adopted by the several States no less than by the Federal Government.

Especially commending the portions of the report dealing with diminished national efficiency due to disease and premature death among our citizens, we urge the adoption of the policy of protecting life and health by States, municipalities, and communities no less than by the Federal Government; and we urge further investigation of all other means whereby the efficiency of individual citizens, and hence of the States and nation, may be increased.

We favor the maintenance of conservation commissions in every State, to the end that each Commonwealth may be aided and guided in making the best use of those abundant resources with which it has been blessed.

We also especially urge on the Congress of the United States the high desirability of maintaining a national commission on the conservation of the resources of the country, empowered to cooperate with State commissions, to the end that every sovereign Commonwealth and every section of the country may attain the high degree of prosperity and the sureness of perpetuity naturally arising in the abundant resources, and the vigor, intelligence, and patriotism of our people.

Ex-Governor PARDEE. I move the adoption of the report of the committee.

(The motion was duly seconded.)

Senator SMOOT. Mr. Chairman and gentlemen of the conference, I wish at this time, as I did in the committee, to reserve the right in voting upon this report to say that I am rather doubtful in my mind as to whether a law can be passed that would be successful in the United States, especially in the western parts of this country, in the separation of the surface rights from the mineral rights. In saying this I simply refer to lode claims and placer claims. I approve of the principle, if it can be carried out successfully, but in my opinion, knowing the country as I do, where lode claims are numerous and especially as to the placer claims, the surface itself is the ground which contains the mineral, and I reserve the right at this time, as I have suggested, to make this statement, so if I am ever called upon at any time to act upon this I will not have my action or vote here pointed out as my position on the matter.

Senator NEWLANDS. I would like to ask the Senator from Utah whether he thinks this report covers lodes and placer claims? Was it not only intended to apply to consumable minerals, such as coal and iron, and not to the precious metals, gold and silver.

Senator SMOOT. I thought that the report was rather sweeping in its statement, because it says, merely, "mineral rights," and is not specific as to what minerals are included, and I therefore took it for granted that in adopting it, it would mean all of the minerals.

Ex-Governor PARDEE. As many in the committee thought it was almost if not quite impossible to make any reservations, the general idea of the committee and also of the commission was and is that this should refer particularly to these great bodies of consumable minerals, and that whatever portion of the surface of the land may be necessary for the working of the nonconsumable minerals of the country would be freely granted to those people who are working the resources of the country for the purpose of securing those minerals, but that no agricultural land should be given to miners and held by them in great tracts for the purpose of holding and controlling at the same time the gold and the iron and other minerals lying beneath the surface.

Senator SMOOT. Mr. Chairman, I presume Governor Pardee knows I am in full accord with that, and the only suggestion I had at this time was that I wanted a record of this, so that no technical matter could be brought up in the future, but that we in this gathering here virtually understand the question and that we are more particularly referring to minerals that can be consumed rather than precious metals.

Senator NEWLANDS. Mr. Chairman and gentlemen, I should like to say a few words regarding the machinery which, in my judgment, legislation should provide for this constructive work regarding the waterways.

In my judgment, the period of agitation is nearly over and the period for actual construction is come. Public opinion is now formed upon the subject of the development of the waterways throughout the country. It has so impressed itself upon the action of political parties of the country that both parties, in recent national convention, have declared themselves unequivocally for the full development of all waterways for every use to which civilization can put them. You will find clear, unequivocal statements upon this subject in both platforms, and it remains now for Congress to carry out the pledges which the great parties have given to the people. This is the real question now before us.

You have appointed a committee consisting of a representative from each State in the Union to appear before the Committee on Commerce of the Senate and urge the views of this conference regarding the development of our waterways. There is not a man on that committee who does not favor the development of our waterways, but the question of the machinery under which that development shall be accomplished is an open question. It is that question upon which they will wish to hear from you. Are you satisfied with the machinery which thus far we have had? The views presented by Members for particular projects are freely aired at the committee meetings. The bills concerning the matters are referred to the Engineer Corps of the Army for their opinion, are then later acted upon by the committees of Congress, and then by Congress itself. Those methods of course have been improved in late years under the admirable administration of Mr. Burton, of Ohio, as chairman of the Rivers and Harbors Committee.

But the energies of Mr. Burton, I imagine, have been directed more in the line of preventing pernicious projects than of advancing real constructive projects. We all realize that Mr. Burton has been an overworked man, so much so that he proposed to withdraw from the chairmanship of that committee at the last session of Congress, because he found that his time was exclusively taken up in its work. He desired to apply himself, as he is well fitted to do, to problems of general statesmanship. If Mr. Burton should retire from that committee, how long will it be before we can get another man who will acquire the same experience and who will manifest the same interest in his work that Mr. Burton has? The difficulty has been thus far that Congress has been endeavoring to do not only legislative work but executive work, and we have not had the assistance in the execution of a great work of a great number of government experts who could furnish us all these various projects in an uncompleted form, determine their merits and their relative importance, and weave them all into one connected and comprehensive plan, and when a project was determined to be feasible, immediately enter upon the construction of the work.

We have been engaged in river and harbor work ever since this Government was formed over one hundred years ago. We have expended over $500,000,000 in river and harbor improvements, and outside of the harbor improvements, many of which have been admirable, we can hardly find any appreciable results so far as the navigable rivers of the country are concerned. We have witnessed the development of the pork barrel, under which process each of the Members of Congress scrambles for position upon these committees, with a view of securing the advancement of his project in his particular district, not engaged in the formation of comprehensive plans, not looking out for the interests of the entire people, but simply looking at the particular project in which the particular district may be interested, and that particular district content provided a large amount of money is expended, whether the project be meritorious or not.

I heard the Speaker of the House of Representatives before the Rivers and Harbors Congress this morning speak upon this subject. He gave the history of legislation upon this subject and showed the advances that have been made, and among other advances declared that in the Fifty-first Congress, nearly twenty years ago, the Government had entered upon the contract system in river improvement, and he held up his head and said, "Thank God for the contract system." Think of a government which has been in existence for nearly one hundred years engaging in river and harbor improvements without seeing the merits of the contract system; and if it takes the Congress of the United States nearly one hundred years to ascertain the advantages of that system, I ask you how long it will take Congress to frame a connected and comprehensive plan regarding the development of our waterways?

I am a Member of Congress, and I do not wish to belittle the capacity and usefulness of that body, but I do say that it has seized upon and held powers for years that do not properly belong to it.

It is the disposition of every person and of every organization to seize as much power as it can and to exercise it, and Congress has been jealous of giving up any portion of its power upon these questions, and will be in the future.

The other day a prominent Member of Congress asked me what I thought as to the advantages of having a commission. He said, "I feel that I can get more from a committee of Congress than I can from a commission." He did not realize the significance of his utterance. He was an advocate of the system that enables a Congressman to get as much as he wants for his particular district or for his particular State, whereas the advantage of a commission is that it does not yield at all to political interests, but it determines those questions according to the scientific relation of them and the scientific importance of the projects, and it knows no district, knows no State, knows no section. I do not believe we can ever enter upon a constructive plan properly that involves this collision of interests that a legislative body will necessarily be involved in.

So the contest which we have before us is not one as to the advisability of entering upon the improvement of our waterways, but as to the methods under which this great work shall be conducted. I wish to say just a few words upon that subject, particularly with a view to impressing certain considerations upon the minds of the committee of this body that is to meet the Committee on Commerce of the Senate to-morrow.

The men who have given most thought to this subject have concluded—and I think they are supported by the judgment of the country—that in order to enter upon this great work it is necessary to have an ample fund provided, and a fund that is not subject in the future to the contingencies of legislation; a fund which, if not kept good by legislative appropriation, will be kept good by bond issues, so that the commission which enters upon this work can plan a long way ahead and can see before it the means with which to engage in consecutive work. Consecutive work is a most important element in this matter; not the disjointed work that we have had in the past; not work here and work there, interrupted now and then by intervals of one or two or three years.

It is also important that we should have a board or a commission—it is frequently styled an inland waterways commission—and the President should be given the power to appoint such a commission and remove the members thereof whenever he sees fit. The responsibility of this great work should, in my judgment, be put upon some one man, and obviously that man should be the President of the United States, in whom all the executive power of the United States is vested. I would allow him to select the officials through whom this work is to be done, with requirement that reports be made to him, with requirement for frequent reports to Congress and submission of plans and estimates and expenditures both to the executive and legislative bodies of the country. I would also provide—and I say I, but I think this is a sentiment indorsed by the Inland Waterways Commission and by the men who have thought upon the subject—for coordination in this work through this commission of the various bureaus of the Government whose work in any way relates to water, such as the Forest Service, the Reclamation Service, the Geological Survey, the Weather Bureau, so that the accumulated experience of all those bureaus and the officials connected with them and the accumulated capacity of all those bureaus and officials can be compiled in the constructive work upon which we are about to enter. Then it is desirable, of course, that that board or commission should have the power of cooperation with States and municipalities and individuals, for we will find that we will have to deal with all in the development of a river to its highest usefulness. In addition to this, we must have provision for bond issues. The fund should be kept good. That fund should be not less than $50,000,000 at the start, set aside in the Treasury for that purpose, with authority to the President of the United States, whenever the fund is reduced below $25,000,000, to issue 2 per cent bonds in order to make the deficiency good, so we will have a continuous fund which can be kept good, by Congress through appropriations, if it so desires, but it must be kept good, if Congress does not act, by the action of the executive department.

These are the essentials : An ample fund, power given to the President to act, full responsibility put upon the President, power given to him to appoint a commission, power to bring into coordination with this commission all the related services of the Government, power, whenever the fund is lessened by expenditure below $25,000,000, to increase the fund.

You will find great objections to this among the Members of Congress. You will find unwillingness to relax power. You will find unwillingness to relax their power of determining what the project shall be; but it seems to me that this commission should be given the full power, with the approval of the President, whenever the project is determined by them to be feasible, to immediately commence the construction of the work. We have had this experience in the irrigation service. There were 15 States and 3 Territories interested in irrigation. After public sentiment throughout the country had determined that national irrigation should be commenced, we found that the sentiment of those States was so divided as to the methods of operation as to where the first project should be commenced, as to what the amount of the appropriation should be, that we finally, in order to avoid conflict among ourselves, which would injure the cause before the entire country, created a reclamation fund out of the sale of public lands and put the entire fund under the control of the Secretary of the Interior, giving him the power to employ engineers and experts, and, whenever he deemed a project to be feasible upon such reports, to immediately enter upon construction, and the result is that after five years of operation the irrigation service to-day can show more effective work than can be shown by the rivers and harbors forces of the country during the entire history of the United States.

The irrigation service has entered upon work with reference to 23 separate projects. It now has in its funds, from the sale of lands, over $40,000,000. Every State in which these works are being conducted is a State that has progressed. The entire service has been taken out of the politicians' hands, and in this respect the pork barrel does not exist.

I will not take more of your time upon this subject when time is so precious, although the subject itself is one that is a constantly broadening sphere of suggestion. I simply wish to impress this upon this conference and upon this committee that is to meet the Committee on Commerce to-morrow. Let them not waste any time upon the general advantages and the general importance of the waterway transportation and of waterway development. Let them address themselves simply to the practical work of organizing a great constructive commission, composed of engineers and experts who can investigate, and after investigation and the approval of a project by the President of the United States, can enter upon immediate construction.

(Thereupon, without further discussion, the resolutions offered by the committee on resolutions were adopted as submitted.)

FURTHER REPORT OF COMMITTEE ON RESOLUTIONS.

Ex-Governor **Pardee**. The committee on resolutions further desires to offer the following:

Resolved, That a joint committee be appointed by the chairman, to consist of six members of state conservation commissions and three members of the National Conservation Commission, whose duty it shall be to prepare and present to the state and national commissions, and through them to the governors and the President, a plan for united action by all organizations concerned with the conservation of natural resources.

Mr. Chairman, I move the adoption of that resolution.

(The resolution was unanimously adopted.)

Ex-Governor **Pardee**. The committee on resolutions has instructed me to present the following:

Resolved, That the question of the desirability of and ways and means for publishing the proceedings of this conference be referred to the joint committee of nine provided for by a previous resolution, with power to act.

Mr. Chairman, I move the adoption of that resolution.

(The resolution was unanimously adopted.)

Senator **Newlands**. Mr. Chairman, at the suggestion of Doctor McGee, I desire to offer the following resolution and move its adoption:

Fully approving the policy of improving the waterways of the country for navigation and other interstate uses of the waters, we urge the prompt adoption of the broad plan recommended by the Inland Waterways Commission for waterway development under an executive board or commission appointed by and acting under the direction of the President of the United States.

(The resolution was unanimously adopted.)

Mr. **Cuttle**, of California. Mr. Chairman, I understand the committee on resolutions considered and recommended with reference to the report of the national conservation committee only. I have been asked to present the following resolution:

Whereas the destruction of the timber on the watersheds of the rivers of the United States causes the flow of water to fluctuate between floods which cause incalculable damage, and extreme low water, which destroys the utility of the rivers for navigation, water power, and water for domestic use and irrigation: Be it

Resolved, That we recommend that the several States enact laws regulating the cutting and removal of timber and slash on private lands to the end that the continuity of the forests of our country may be assured; that damage from floods may be prevented; that a more uniform flow in rivers may be maintained for the benefit of navigation, water power, and water for domestic use and irrigation.

Mr. Chairman, I move the adoption of this resolution.

(The resolution was unanimously adopted.)

Mr. **Evans**, of Pennsylvania. Mr. Chairman, I desire to bring out in this national conservation work these seventy-odd national bodies, at least national in scope, which were thought worthy of being invited here as conferees. We of course desire their good will. They are worthy of consideration in forming a national policy for this work. I move you, therefore, that these conferee bodies be invited to send in, to be incorporated in the proceedings of this meeting, their suggestions and views as to how they can cooperate in this conservation work.

Mr. **Rice**. Mr. Chairman, I would like to suggest that that motion include the proposition of sending from some central source to these separate organizations the information that may thus be contributed. Let the National Conservation Commission receive the advice and suggestions from the organizations throughout the United States, and then that advice should come back to them in a compact form.

The **Chairman**. As I underestand the suggestions, they are that the national organizations invited to attend this conference be asked to give their advice and suggestions to the committee of nine which is to be appointed as to how they may best join in this movement, and that the committee of nine thereupon communicate with them in turn, transmitting to these various organizations the suggestions and advice thus received and tabulated by the committee of nine.

(The suggestions were unanimously adopted.)

Governor **Noel**. Mr. Chairman, I move that the chairman and secretary of this conference be added to the committee of nine and constitute a part of that committee.

(The motion was unanimously carried.)

The **Chairman**. By the courtesy of the meeting, I have an announcement to make.

I take upon myself the liberty of suggesting to the conference that it authorize all members who have papers or discussions, which they have not been able to submit, to send them in for incorporation in the final report. That matter has been submitted to this committee of nine, and it seems to me that the conference itself ought to take action upon that matter. Without objection. the chair will assume that the secretary of the conference, pending the action of the committee of nine, will be empowered to receive these communications and hold them.

Second, I desire to suggest that you allow your chairman to suggest to the authorities of the hotel the appreciation which undoubtedly you have, as I have, of their courtesy and the way they have treated us while we have been here.

Governor **Ansell**. I offer that as a motion, Mr. Chairman.

(Motion carried.)

Mr. **Lay**, of Alabama. Gentlemen, I move that we extend our thanks to our worthy chairman for the many courtesies and the patient and able manner in which he has handled this meeting, and for the energetic work that he has done in behalf of the cause for which we are here assembled.

Mr. **Cuttle**, of California. I second the motion.

(Motion carried.)

ANNOUNCEMENTS.

The CHAIRMAN. I have two more announcements to make, and then there are one or two gentlemen who ought to say a word before we adjourn.

In the first place, the Vice-President, Mr. Fairbanks, has requested that I give notice that all members of this conference are invited to a reception at his house this afternoon between 5 and 6 o'clock, at 1701 K street.

Second, may I ask you not to forget my mother's invitation and my own at 9 o'clock this evening, at 1615 Rhode Island avenue, it being understood that this invitation is not only for the gentlemen who are members of the conference, but to the ladies who are members and to the ladies who may have accompanied the gentlemen members. We greatly hope to see all of you there.

Will you, for two or three minutes apiece, listen to two or three gentlemen who have been trying to get recognition, provided they limit themselves to that time?

MR. EDWARD G. ACHESON, PRESIDENT OF THE AMERICAN ELECTROCHEMICAL SOCIETY.

The CHAIRMAN. The first gentleman I shall call upon to address you will be Mr. Edward G. Acheson, president of the American Electrochemical Society.

Mr. ACHESON. Mr. Chairman and fellow conferees: I appear before you as president of the American Electrochemical Society, and I am very grateful for the opportunity to bring to your attention a few facts that justly entitled electrochemistry to be considered one of the most important factors in the conservation of our exhaustible natural resources by the utilization of water power.

Since this conference convened we have had it impressed upon us that we are the first to take an active national attitude toward the conservation of our great resources. We have been told the lives of some of our most valuable assets, as the coal, oil, and iron, are to be measured in one-half, one, two, or three centuries. A century may be long when measured by our lives, but quite short in the life of a nation or in the span of life on earth. It is indeed rather startling to me when I think of the fact that my own short life has covered the one thirty-eighth part of the period since the beginning of the Christian era, and it is within this relatively short period that much the greater part of the consumption, destruction, and waste of the valuable and most essential resources have occurred.

I believe I am correct in stating that the most important of all the elements to man, or at least the one that enters the most frequently into his manufacturing and commercial life, is carbon. Nature provided a certain amount of carbon in fixed chemical combinations, as our natural resources, coal and oil, which we have been consuming and wasting in a prodigal manner. The total amount supplied by nature is limited. Our experts now know approximately the amounts we have in stock and how long they will last, for end they surely will.

These two resources are mainly being consumed in the production of what the scientific people call wave motions—light waves or heat waves—both of them essential to our way of living, either for the production of light to our eyes, warmth for our bodies, or heat for our domestic, manufacturing, and transportation uses. There are other and perhaps unavoidable uses for our fixed carbon, as, for instance, a reducing agent in metallurgy, the making of carbides, for the making of our arc-lamp carbons, etc. For that portion of the carbon consumed in producing wave motion, and it represents a large part of the total, a ready and everlasting substitute is to be found running to waste in all sections of our great country—our natural resource, water.

It has been so willed and provided that men, while consuming the store of fixed carbon provided for them, have learned to produce these all-important wave motions at will from any source of mechanical motion, and by the utilization of our everlasting flow of waters we can readily produce light or heat and conserve the carbon in our coal and oil for those purposes for which we have not, as yet, discovered a substitute.

To attain this desired end we must begin with conservation of our forests in order that we may have this everlasting flow of the water, and the water must be enslaved to do the work that has been borne by our fixed carbons.

In the carrying out of this work a threefold object should be in view—the production of power for railway transportation, manufacturing and electrochemistry, transportation by waterways and irrigation. Such a project carried to completion would usher in the electro-chemical age, and I predict it would receive an enthusiastic reception.

Electrochemistry, in its more modern form and especially as applied to metallurgy, is still young, taking form in 1888 at the time of the beginning of what is now one of our largest electrochemical industries—the manufacture of aluminum by electricity. Within the twenty years since that date, great strides have been made, a number of chemical and metallurgical processes have been converted into electro-chemical and electro-metallurgical ones in a very successful way and to the advantage of the industrial world, while at least five new materials, previously unknown, are now sold in the world's markets, they having been made possible of production by electrochemistry.

Electrochemistry is in fact a creator. It transforms the cheap and perchance useless wastes into products of value. It works either with the silent invisible electric current, or by the stress of heat. It lends itself to the ready adjustment of temperatures from that of the atmosphere to the highest attainable on earth, one in which the metals, rocks, and all things earthly disappear in vapor. It tears asunder the elements as joined by nature and rearranges them under man's guidance. Thus it has made ordinary sand unite with carbon and form the well-known product "carborundum." In another instance it converts "culm"—the waste material of the anthracite coal mines—into graphite of wonderful purity. In another case it has enabled us to extract from sand metallic silicon, a beautiful silver-colored body, which, although very new, has found a place in our arts and manufactures. As another example, it fuses in the electric furnace the soft amorphous bauxite into a condition suitable for use as an abrasive and refractory material and known as "alundum." And in still another case lime and carbon are made to unite in the electric furnace to form the valuable product, carbide of calcium, now well-known as the source from which our familiar acetylene light is obtained. In this last mentioned example, the world is not only furnished a new and convenient light, but with greater economy of our natural resources. And all this without calling upon our exhaustible natural resources, but by the utilization of the energy of a waterfall.

Electrochemists are now earnestly at work on problems of even greater magnitude than any I have mentioned, as, for instance, the electro-metallurgy of iron and steel, and the fixation of the nitrogen of the air. The commercial fixation of nitrogen gives us a ready and inexhaustible source from which to draw the world's future supply of fertilizer, thus averting the great calamity that has stood specter-like before us—the exhaustion of the earth's fertility. The commercial fixation of nitrogen is now being carried out in Norway, where cheap and abundant electric power can be had. Indeed, Europe is now preparing to use 400,000 horsepower, developed by water, in this line of manufacture, and not to be outclassed, plans are now about perfected to build a very large plant in America, not, however, within the United States, but in Canada at Niagara Falls, where power is more abundant and cheaper than on our side of the cataract, and even then it is twice as costly as in Norway.

Electrochemistry is a power consumer. It requires not only much power, but cheap power. The first hydro-electric power plant of considerable magnitude in this country was put into operation at Niagara Falls in the fall of 1895, since which date quite an electrochemical center has sprung up at that point, and there is now approximately 125,000 horsepower being utilized in the work of producing phosphorus, carbide of calcium, alumdum, caustic alkali, bleaching powder, metallic sodium, aluminum, metallic silicon, carborundum, artificial graphite, chlorate of potash, and other products, the united values of their annual production amounting to many millions of dollars. These Niagara Falls products may, to the great industrial world, seem small, but let me impress on you that they have been developed within thirteen years, that they cover a varied field and they are but a promise of the future development when we have cheap power, they being produced with power costing three to four times the price of similar power in Norway. And when it be remembered that the conservation of the water in Norway is in the interest of power only, we may hope for much when the expenses are carried by power, transportation and irrigation.

To the optimistic electrochemist, it seems possible for his profession to transform many of the chemical and all or practically all of the present metallurgical processes into electrochemical and electrometallurgical ones, and to vastly extend the list of products employed by the industrial world, thereby conserving our fuels by the utilization of water power and conserving our natural minerals by the substitution of artificial ones.

In order that we may obtain the benefits possible of being derived from electrochemistry, it is essential that the art be not crippled by having our natural resources—the water powers and minerals needed by the art—monopolized and held in the selfish interests of a few. The remarkable progress we have been making has been due, to a large extent, to the inducements held out by our beneficent and more or less efficient patent laws, in rewards to the inventor for his labors. A private monopoly is guaranteed him, covering a period of seventeen years, in return for original work he has accurately described to the public, and at the termination of this monopoly, he is presumably, well on the road to permanent success, and decidedly in advance of any possible competitors; still there are men, and particularly those who have taken over the interests of the inventor, who would perpetuate this original monopoly by laying hands on the natural resources of the country that are vital to the inventor's methods or processes, and by monopolizing them prevent others from competing by later and even more efficient processes, and thus they thrive at the expense of their fellow men, at the same time largely defeating the intent of the contract between the inventor and the Government, as contained in the Letters Patent.

In conclusion, I would say no one is, probably, more keenly alive to the possible advantages that should accrue to the world, from this great conservation movement, than the electrochemist, nor should any other profession render more valuable services, following as he will the hydraulic and electrical engineers and putting to work the power they develop for the better conservation of our natural resources.

MR. E. W. WICKEY, REPRESENTING THE FARMERS' NATIONAL CONGRESS.

Mr. WICKEY. Mr. Chairman and gentlemen, I would feel indeed a very weak representative of the great producing class of this country did I not take advantage of this opportunity to assure this convention that you have the hearty cooperation and sympathy of the farmers of this country.

The day of the bewhiskered farmer is passed, as he has been represented in the press up to recent times. The farmer of this country is no longer the man who buys the gold bricks. They are now sold to the man on Wall Street. The farmer of this country is a man to-day who is progressive; one of the most progressive of this age. No great movement of this country has succeeded unless it has been endorsed by the farming class.

It has been suggested here by the governors that there is no North, no South. I want to say to you that the Farmers' National Congress, which I have the honor to represent, was the first national organization in this country to begin to wipe out sectional lines. It was organized by the planters of the South and the farmers of the North, and our officers have alternated between the different sections of the country. We meet one year in the North and the next year in the South, the third year in the West, and the fourth year in the East. Our last session of this year was at Madison, Wis. The committee to-day decided to accept the invitation of North Carolina, and we will meet next year in the city of Raleigh.

We were recognized by both the presidential candidates of the two dominant parties, and Mr. Bryan and Mr. Taft addressed our congress this fall, and we have reasonable assurance that Mr. Taft, as President of the United States, will address our congress when we meet next year.

The farmer is coming to his own. He is being recognized as a power in this land. We no longer think in dollars; we think in hundreds of thousands, as does the banker. The expenditure of millions of dollars in improvement of our natural waterways is no longer alarming to us. The products of the fowls of our farms would improve all the waterways of the land and provide all the money that the National Rivers and Harbors Congress is asking the Congress of the United States to appropriate. The hens of our country would furnish these $500,000,000 in one year and leave enough over to replace the money, Mr. Chairman, that has been spent up to this time on the Panama Canal!

I say to you that the farmer is coming to his own. I want to say that this is largely due to the chairman of this conservation commission and to the President of the United States and to our many great men who are recognizing to-day the power of the farmer. We do not say much. We are not long-winded, but back in our own districts the Congressmen of the United States are beginning to recognize that we speak at the ballot box, and we do not do much kicking; but the man to-day who fails to pass progressive legislation demanded by the farmer soon finds his place at home and not in Congress.

I say to you in conclusion, and repeat it emphatically, that the farmers of the country are in favor of this great movement for the conservation and development of our natural resources. We believe in the development of our waterways. We to-day are spending money for automobiles, for pianos, for improved heating appliances in our houses, for bath rooms, and all of these luxuries of life. We are keeping our money back in our home towns and not sending it to Wall street. Gentlemen, when you want to accomplish the big things, remember the farmer. We are with you on this proposition, and we care not how it is carried out, so the policy and plan is an honest one, as we believe it will be if left to the President of the United States, as has been suggested here. I thank you.

MR. BERNARD N. BAKER, CHAIRMAN OF THE MARYLAND STATE CONSERVATION COMMISSION.

I have listened with great interest to all that has been said at this meeting, and I would like to add, as the representative of Governor Crothers, of the State of Maryland (at the same time expressing to you his regrets that he is not able to be present), that you can count upon the hearty cooperation of our State in the magnificent work you are doing. We would like to do our part, and stand ready to do what we can. Maryland occupies a unique position, at least in forestry, as, I think, it has a larger forest area, in proportion to the total area, than most of the older States. It also has but few water courses that have not already been developed in the way of their powers. If you could conserve to us our terrapin and canvas-back duck you would give a lasting blessing to all our citizens. But this, unfortunately, you can not do.

It has occurred to us that possibly we might be of more assistance in trying to forward the educational features of this great work, and with this object in view, I would most respectfully ask of this commission the consideration and adoption of the following resolution:

"*Resolved*, That a committee of five be appointed by the chairman to consider and report the best way to place before the boys and girls of our country, by educational methods, the necessity for the conservation of our national resources."

I was very much interested in hearing from our friends of the great men of this country—Washington, Jefferson, Lincoln, and Roosevelt. Where are the future great men of our country except among the boys of our schools to-day?

Whatever practical measures be inaugurated in the conservation of national resources, there will be no particular effect save as popular support, which is sincere and intelligent, is secured for such measures. Opposition to practical measures will arise, if any, from those who would gain personally by the exploitation of these national resources. Those who will gain especially by their preservation will be the men and women of future generations; that is, those who are boys and girls at the present time. If firm and intelligent support for practical measures can be secured from these boys and girls, and from them as they grow to manhood and womanhood, by enlightening them as to the purposes of the commission, and awakening their sense of obligation to the nation, then a permanent work can be accomplished. The high schools of the country are becoming very powerful in their influence over their young people, and explanations illustrated by lantern slides showing the national resources and explaining the necessity for their preservation and the practical measures therefor, can be made for these high schools throughout the length and breadth of the country, winning the active sympathy and support of their students. Emphasis can be laid upon the duty of these young men and young women to take personal interest in and to exert themselves in an honorable way toward the enforcement of whatever laws may be passed for the preservation of these national resources. The photographs taken by the government departments will be ample in many ways for the purposes of these illustrated lectures for high schools. The necessity for replanting forests, for preventing pollution of streams, for retarding exhaustion of minerals and prevention of waste, and the success of other countries in such matters can be explained from photographs. The important work already inaugurated by the Department of Agriculture, looking toward the importation of the most important seeds for utilization of the varied soils and climates, can be dwelt upon. The work of experiment stations and agricultural colleges in the improvement of methods of farming and gardening can be noted. The appeal to the high-school boys and girls for cooperation with the Commission in its important work can be made overwhelmingly convincing, and can be laid upon them as a matter of patriotism that they be energetic and wide awake in their support of the cause. It can be made a duty that they take their part in the campaign for national thrift, and it can be shown clearly that national thrift and personal thrift are but one and the same thing.

The practicability of such an educational campaign as outlined is apparent, if one considers the high-school organization. Most high schools have large assembly halls, equipped with electric lanterns, and are in the habit of having general lectures of educational value. A proposal that an illustrated lecture on national thrift and the preservation of national resources be given would probably be accepted by the great majority of the high schools of the country. That such a lecture could be made intensely interesting and effective in its appeal to the boys and girls seems quite certain, in view of the natural personal interest which could be aroused.

A second gain from such an illustrated lecture would be the arousing of interest in country life as contrasted with city life. A portion of the lecture could be devoted to the explanation to city high-school boys and girls of the great opportunities open to many of them, if they would but leave the great cities and devote themselves to country enterprises. Assistance thus could be rendered in the campaign for the prevention of congestion in our cities. The agricultural high schools throughout the country would welcome assistance in their efforts to keep the country boys and girls on the farms.

Inasmuch as sincere patriotism lies at the foundation of the work of this commission, and the effort is to establish practices in the conservation of national resources which will benefit future generations, it is clearly wise to enlighten the high-school boys and girls on this whole matter, since they are the ones who, as men and women grown, will profit by the policy, and upon whom will rest the responsibility for its enforcement and continuance.

Many of us here to-day are men, who, in the natural course of events will not personally enjoy these benefits; the boy and girl to-day in our schools will. Let us show them what we are trying to do for their benefit, and secure their hearty sympathy and cooperation in our work.

MR. HENRY A. BARKER, CHAIRMAN OF THE RHODE ISLAND STATE CONSERVATION COMMISSION.

Rhode Island, though the smallest in her area, is not the least among the United States in her recognition of the great doctrine of conservation. Always has she been foremost in her support of new methods and new principles, destined to promote advancement in the course of civilization. Traditionally she has held up the beacon light, guiding the world toward constitutional government and to the precious doctrine of religious liberty. The first of all communities to formally declare herself as a sovereign State; the first among the American colonies to back up her asserted principles by force of arms.

The name of Rhode Island is written large in the victory of the emancipation of mankind.

Rhode Island, therefore, may not consistently stay out of the procession now marching onward toward conservation and national development, nor can it occupy a rear rank in a movement so enormously significant in its effect upon the welfare of the nation through all the years to come—a movement mightier than most men now foresee—mightier, perhaps, than any man may dream.

Rhode Island, which has been first in war and first in her assertion of the sovereign right of man to constitutional government, must rejoice in her opportunity to be among the first in a splendid enterprise of peace.

DR. CYRIL C. HOPKINS, OF THE UNIVERSITY OF ILLINOIS AND MEMBER OF THE ILLINOIS STATE CONSERVATION COMMISSION.

I beg to urge upon this conference that larger consideration be given to the preservation of the fertility of the common American soil. You have heard it stated here that by means of irrigation it is possible to reclaim hundreds of thousands of acres of land in the arid or semiarid States. It can also be said with equal truth and it should be said with greater emphasis that under our most common farm practice we are reducing the fertility of not merely hundreds of thousands of acres, but of the great body of American farm lands, upon the preservation of which depends absolutely the prosperity of the United States.

Within a hundred miles of the spot where the first permanent English settlement was made in our country, you can to-day buy hundreds of thousands of acres of arable land for $10 an acre, land that was once valued at $50 an acre, and would now be worth $100 an acre if its fertility had been maintained. And I do not include in this statement any reference to lands that have seriously suffered from soil erosion, but I refer only to great areas of nearly level or gently undulating farm lands whose productive power has been almost destroyed by a hundred years or more of common cultivation by American farmers.

The great material problem of the United States is not in the development of the waterways, not in the preservation of forests, and not in the conservation of our coal and iron, important as these all are, but the problem that is vastly greater than all of these is to bring about the adoption of systems of farming that will maintain or increase the productive power of American soils.

We must not deceive ourselves with general statistics which show some increase in average crop yields in some States. Thus, in my own State of Illinois the average yield of corn has increased in the past ten years, but does this prove that Illinois soils are growing richer? No. Let me tell you that during the past ten years the annual corn area of Illinois has increased from 7,000,000 to 9,000,000 acres, and the added 2,000,000 acres are the richest black soil of the State, reclaimed by dredge ditching and tile drainage, while the 7,000,000 acres are producing smaller crops than ten years ago.

The practice of the present art of agriculture tends toward land ruin. If any of you know anything of American agriculture, you know that as a general rule old land is poorer than new land. Therein lies the fact that points toward future poverty for our children. The United States is one of the great agricultural countries, and without agriculture America would be nothing. Without agriculture our coal and iron would remain in the earth, our forests would be uncut, our factories, railroads, and waterways would be abandoned, and our cities depopulated.

If the art of agriculture has reduced the productive power of American soil, then the science of agriculture must restore it; and the key to the problem for our most common agricultural land is the element phosphorus. Phosphorus is the only element of value contained in the mineral called phosphate. There are three elements of plant food that have recognized market values—nitrogen, phosphorus, and potassium—and the inventory of our natural resources must include the supply of each of these three elements.

The nitrogen can be gotten from the air, not only without expense, but with profit in the getting, because such crops as clover and alfalfa, which by means of symbiotic bacteria have power to utilize atmospheric nitrogen, are valuable crops to raise for their own sake, and where these are plowed under liberally, either directly or in manure, nitrogen is thus supplied for the production of any other crop.

Potassium is one of the abundant elements in the earth's crust, and consequently in all normal soils. Thus, several hundred analyses by the Illinois Experiment Station have shown that the average corn-belt land contains sufficient potassium in the plowed soil for a hundred bushels of corn per acre every year for as long as the time since Christ walked among men—or sufficient potassium for the average corn yield of the United States every year for as long as since Adam began to till the soil.

One hundred bushels of corn contains 19 pounds of potassium and 17 pounds of phosphorus; and, while the average crust of the earth contains 2½ per cent of potassium, it contains only one-tenth of 1 per cent of phosphorus; and the most common agricultural lands of the United States contain in the plowed soil no more total phosphorus than would be required for a crop of a hundred bushels of corn per acre during the full life of one man.

For the adoption of systems of permanent agriculture under which our common lands shall grow better instead of poorer, the nitrogen problem is to secure it from the absolutely inexhaustible supply in the air, and the potassium problem is to draw it as rapidly as necessary from the practically inexhaustible supply in the soil, while the phosphorus problem is to get all we can and keep all we get.

But what are we doing? We are exporting every year for less than $6,000,000 sufficient phosphorus for the production of $600,000,000 worth of corn, while the scarcity of the element already limits the yield of corn on the commonest corn-belt land.

I close with a single illustration to show the possibility of increasing the productive power of the land with proper treatment and the certainty of soil depletion even under a good crop rotation without the addition of plant food.

For sixty years at Rothamsted, England, the oldest agricultural experiment station in the world, a four-year rotation of turnips, barley, clover (or beans), and wheat has been grown on Agdell field, where the soil is of normal composition. There are three sections in this field; no plant food has been applied to one, minerals, including phosphorus, to the second, and the same with nitrogen added to the third.

As an average of the last twenty years, corresponding to the average yield just fifty years from the beginning of the experiments, the following results were obtained:

Average crop yields per acre in Rothamsted, four-years' rotation, after fifty years.

Soil treatment.	None.	Minerals.	Minerals and nitrogen.
Turnips ....pounds..	963.0	25,278.0	40,947.0
Barley ....bushels..	13.7	22.2	29.2
Clover ....pounds..	773.0	3,898.0	3,450.0
Beans........bushels..	15.9	28.3	19.6
Wheat ....do....	24.3	38.4	36.4

Beans were grown where clover failed.

When the American farmer had depleted most of the lands of the Eastern States he moved into the Central States, and he is practicing the same ruinous systems there, and if these systems are continued, wherewithal shall America feed her own people a few years hence?

I say to you famine in America is easily possible. There may be no need for sensation, but there is need for sense.

I say to you if we are ever to adopt systems of permanent agriculture in America it must be done while we are prosperous, for an impoverished people is at once helpless and soon ignorant. Only the prosperous can afford education. It is impossible for a poor farmer on a poor farm to invest in the permanent improvement of his land if he has nothing to invest—if it requires every dollar he can secure from the sale of every salable product to support his family and pay his taxes.

Whenever the hundreds of thousands of acres of level or gently undulating depleted or abandoned farm lands of New York and old Virginia are redeemed and made equal to the newer lands of the Central West, which are now in their prime, paying good interest on $200 an acre, then, and not till then, can there be any other material problem of the United States that compares with this in reference to the future welfare of America.

MR. EDWARD R. TAYLOR, CHAIRMAN OF THE CONSERVATION COMMITTEE OF THE AMERICAN ELECTROCHEMICAL SOCIETY.

Mr. Chairman, ladies, and gentlemen, I address you as chairman of the conservation committee of the American Electrochemical Society.

In the wastes referred to in the introductory part of the very able report of the conservation committee to President Roosevelt I wish had been included the waste of running water. This waste in the State of Alabama alone was admirably shown by Mr. Lay yesterday to be equivalent to the running over a precipice of 11,000,000 tons of coal, and if saved and applied as it should be is capable of saving that much coal to the State, at the same time making navigable several of its rivers the year round.

The great bulk of our people in this great country live on the most valuable land near the level of the sea, and very few such realize the immense possibilities for water storage by lakes and reservoirs in the hill country.

About two weeks ago I visited a farm on the headwaters of the Delaware River through which runs a brook from which the farmer derives 25 horsepower and lights his building and house with the electricity generated therefrom. He could also do the cooking, heating, and lots of other things about his place with the same power. This is now the only power developed on that brook, which, he told me, formerly ran 89 sawmills. If each of these sites could develop 25 horsepower, which is a fair assumption, that little brook alone represents a waste of 2,206 horsepower and represents the running to waste of 26,460 tons of coal; and yet those very families are drawing coal from the railroad 5 miles away and letting all of this power go to waste.

But by storage reservoirs in this same hill country the above-estimated power could easily be doubled or trebled, or made even five times as much. Multitudes of other streams in the same vicinity could be similarly treated and the electricity generated at every site ted to a common center, every farmer and resident supplied with all he wants to use and the remainder used to run electric cars for their benefit and for lighting and heating the buildings in the near-by towns and for manufactories that could be built up, or sent on high-tension wires to large cities within reach. From 100,000 to 300,000 horsepower could be developed near the center where this creek joins the Delaware River, the buying of coal practically cut off, and new pleasure added to life for the inhabitants; at the same time flood waters restrained from spoiling the more valuable land near the sea and navigation improved. This farm is about 1,600 feet above sea level, and every cubic foot of water per minute from that level, passed properly through water wheels to the sea, would represent 3 horsepower or the saving of 36 tons of coal per year. May each State develop one or two such centers of power as object lessons and to show what can be done. Do not say it is small; it is big when we aggregate the possibility.

This is by no means an exceptional possibility, but a typical illustration of multitudes of opportunities in the hill country throughout our broad land, and, if generally so used, would develop millions of horsepower, make year-through navigable rivers and reduce to minimum flood damages. Every lowland State in the Union is directly interested in the remote hill States that are the source of these mighty rivers, and should insist that water that can be impounded into lakes there and converted into power of great value shall not run to waste and overflow their valuable lands. Truly our brotherhood is wide and large. Therefore even this is a work for the whole country, and the General Government should aid in making some illustrative developments on small streams. "Look not every man on his own things, but every man also on the things of others."

But I have a much larger subject to speak of. The level of Lake Erie is 565 feet higher than the Hudson River at Albany, and is downhill all the way except a sag of about 20 feet between a little east of Rochester and a little west of Rome. This can be overcome either by raising the level of Cauga Lake and changing the course of the canal to higher levels than now contemplated or cutting down the Rome level to make a complete lock down ship and power canal from Lake Erie to the Hudson River.

New York State is committed to a barge canal which takes no cognizance of power developed in this electrical age even for the haulage of its own boats.

A ship and power canal thus constructed through the State of New York is estimated to be worth, for power alone, by Engineer McClintock, at $500,000,000, and he made earnest protest against committing the State to the barge canal it is now building. Niagara Falls is the seat of power that it is to-day because of the utilization of about 140 feet head of water. But what would it mean to utilize 500 feet head of water distributed through the grand State of New York, and three-fifths of that within 175 miles of New York City, with a harbor for large vessels all along the way, and the conversion of western wheat in transit into flour, and the manufacture of crude materials into higher values. The commerce of the Great Lakes is stupendous and should be continuous to the sea, and is a suitable work for our National Government to make possible. For navigation purposes a canal through there can be used but about eight months per year, but its power can be used the whole year through. Selfish interests in Buffalo and New York City committed our State to a barge canal exclusively for navigation; but even so, our great Inland Waterways Commission should step in and right the wrong and give us a ship and power canal commensurate with its great earning power, and the stupendous transportation interests of the West crying for an adequate outlet to the sea, a thing they are bound to have.

MR. JOHN B. ATKINSON, OF KENTUCKY.

Mr. Chairman and gentlemen of the Conservation Conference: As a representative of Governor Willson, of Kentucky, who greatly regrets his inability to be present on this occasion, I can tell this meeting that much interest in the conservation of the forests is being manifested in my State.

Women's clubs have become greatly interested, and good work is being done by them. It was my good fortune to address recently the Alumnæ Club of the Girls' High School, of Louisville, on "How we plant trees in Kentucky," illustrating with photographs and transparencies the young planted forests at different ages. The ladies of the club will give talks on practical forestry in all the public schools of the city, and illustrate with photographs what can be done in the way of making new forests, thus reaching 27,000 school children in one city alone.

Women's clubs in many cities of the State are asking information and pictures for the use of the clubs and schools. When the women take up any great subject, we all know that great good will follow.

Nor are the women and children alone interested. Large corporations owning forests and coal properties are gathering information, and slowly, perhaps, imbibing the fact that there is money saved in the more careful cutting of timber. One large company has planted this autumn and winter 1,000 bushels of walnuts (over 300,000 nuts) on 1,000 acres of woodland that had been partially cut off, and is inclosing the tract with a fence to keep off cattle and other stock. The railroad companies are planting trees in large numbers also.

Kentucky was one of the best timbered States in the Union, and still has more than half its area covered by forests in various stages of preservation and offers at this time an opportunity that few States possess of rebuilding them to a high condition of efficiency and perpetuity.

A close partnership exists between the forests and the mines. Timber is as necessary in mining as is labor. Hence the mining man is especially interested in having perpetual forests. It now takes the annual growth of at least 6,000 acres of forest to raise 1,000,000 tons of coal in Kentucky.

The mining company with which I am interested began planting trees twenty years ago. It came into possession of many acres of worn-out farm lands as well as of large areas of forest. Corn and tobacco had been the principal crops grown by the farmers and when the soil became so poor it would not grow corn the fields were turned out and new ones made from the forest; the trees girdled and finally burned and a new start made with tobacco and corn.

By judicious fertilization and cultivation 2,000 acres of the worn-out lands were brought back to fertility and now produce excellent crops. It had become evident to the management of the property that judicious cutting of the timber for mining purposes was necessary to perpetuate the forests, and it was also determined to plant the vacant cleared land with trees. The black walnut was selected, because of the value of the wood and the readiness of planting. The ground was prepared as for corn, and the walnut with the hull on was planted in the autumn when the nuts matured. The nuts were planted 4′ by 4′ or 2,722 nuts to the acre, being covered by 1 inch of soil. The young forest was cultivated the same as corn for three or four years, and then sown down with blue grass. The spacing of the walnuts 4′ by 4′ was to get a growth upward and also save pruning; the trees to be thinned out from time to time, which was done by cutting down the tree, it being found that it was not profitable to transplant. Far better to plant a nut where a tree was desired. Blue grass always grows under walnut trees, and when the young walnut forest gets to be 10 or 12 years old the trees are high enough and strong enough not to be injured by cattle grazing, and we have walnut trees, blue grass and Jersey cattle growing together. While this is not the rule of forestry to have cattle and trees together, the walnut forest may be considered the exception.

When we began planting trees twenty years ago we had little knowledge of the ages of forest trees, or how long it took nature to produce a forest. A study of stumps was taken up, and the ages of the various trees cut for mining purposes determined. From the facts collected during the twenty years past is made a table of the time it takes certain trees in Kentucky to grow to a diameter at the stump of 12 inches. This is not an infallible table, but is based on actual tree growth as observed in the forests, and has no reference to isolated growth or unusual conditions.

The pin oak will grow 12 inches diameter in forty years.
Black locust will grow 12 inches diameter in forty-five years.
Tulip will grow 12 inches diameter in fifty years.
Black oak will grow 12 inches diameter in fifty years.
Black walnut will grow 12 inches diameter in fifty-six years.
Texas red oak will grow 12 inches diameter in fifty-eight years.
Sweet gum will grow 12 inches diameter in sixty-two years.
Ash will grow 12 inches diameter in seventy-two years.
Hickories will grow 12 inches diameter in ninety years.
White oak will grow 12 inches diameter in one hundred years.

The trees so far planted for forests are the black locust (Robinia), catalpa speciosa, walnut, and tulip (Liriodendron). Since 1887 this company has planted over one million black walnuts on 170 acres of farm land, and in vacant places in the forest. Since 1905 we have planted 110,000 black locusts on 162 acres of land. The seedlings are planted 8 by 8 feet, the same as locusts. We have planted 20 acres of tulip trees (Liriodendron), or 435 trees to the acre 10 by 10 feet. All the young forests are cultivated for three or four years and are always under fence. This company will plant in the spring of 1909 over 60,000 catalpas and 40,000 locusts. It has already planted this year 100 bushels of walnuts (30,000 nuts) in vacant places in the forests.

The question arises, How can landowners be induced to plant trees?

To me the answer is, take off all taxes on land growing young forests, and when productive, tax the product only. I believe this same rule should apply to all forests.

If the legislature of a Commonwealth can protect quails and rabbits with its game laws, it surely can protect the trees. If the owners of forest lands in Kentucky could be induced, or compelled, to fence them against all kinds of stock, and then cut healthy trees, not less than 16 inches in diameter, there would be no question of the perpetuity of its forests.

DR. GEORGE F. KUNZ, PRESIDENT OF THE AMERICAN SCENIC AND HISTORIC PRESERVATION SOCIETY.

The beautifying of the country village or of the farm; the utilizing of the land by the roadside, in place of allowing it to degenerate into a weed bed; the building of proper roads, and the fencing in of attractive points, will do much to keep the young man of the farm where he belongs, where he will be most happy, and where his labor will increase the annual sum of our agricultural production, the greatest asset of the nation. To attain this end there should be some concerted action on the part of the National Government, through the Department of Agriculture, cooperating with the Grangers, the board of state fairs, the county fairs, the Epworth League, and the many organizations which are working to make farm life attractive, and which by their efforts have raised the intellectual level of the farmer, stimulated his interest, and increased the productiveness of his labor. Either the Department of Agriculture, or the National Conservation Commission can easily come into direct contact with all these organizations.

For the realization of these aims, brief pamphlets, or, better still, a few pages issued monthly—to be so short that they may be read at the meeting of every Grange or public gathering of farmers, and to treat, one month in advance of the planting time, of the care of stock, new fertilizers, farm products likely to be in demand, and the abundance or shortage of crops in the various parts of the country—will do more good than millions of scientific and complex works that only specialists can understand, and yet will lead to an appreciation of the latter in the course of time. This will prepare the way for the elaboration of some system whereby every village throughout the entire land will be enabled to set aside a number of acres for a village park or green, the amount of land to be dedicated to conform to the resources of the village. It frequently happens that a most unproductive tract is the most beautiful from a scenic point of view. In proximity could be located the village cemetery; and if such a tract were beautified and planted with typical trees, supplied either by the Nation or the State, or else by the local committees or private enterprise, it would do much to educate those who lack the facilities enjoyed in cities.

In addition to this certain flower seeds and plants could be furnished and—what would also be of great value—a small tract could be assigned for the children to cultivate as a garden. Thus, in a community where there are thousands of acres of land, 10, 20, or 50 acres could be set aside for the furtherance of village improvements, and parcels of land suitable for the purpose could often be obtained from town-tax sales, as a gift or as a united contribution. There should be the wood lot for the poor and needy; the playground and other places for recreation; the small botanic garden, with its typical trees and plants; and the small experimental garden for the children, where they could be taught the principles of gardening and at the same time have the opportunity to earn some pennies for pocket money, something a farmer spares with such difficulty and often so grudgingly that the child becomes only too willing to leave home and try his fortune elsewhere. Besides this, however, the children should be taught to suppress the weeds along the roads so that grass or productive plants may replace the wild luxuriance of unsightly weeds. The children should also be encouraged to gather up the stones from the highways, making the roads more sightly, easier to ride over, and also safer, thus saving many lives in the course of the year.

But we must not forget the power of historic associations in fostering interest in the town or village. Gatherings should be held on historic days, addresses delivered by the best talent the town affords, and the local children should take part. There should be placed in every part, or reservation, or village tract, a signboard of wood or of stone, bearing the date of the settlement of the district, and the record of any historic happenings connected with it, and also a simple map, showing its distance from other neighboring places. If there are any prominent historic points within the limits of the village or country, such as old milestones or houses of notable people, these should be marked in a very simple manner on tablets made of terra cotta, for instance, which could be manufactured at the nominal cost of a few dollars each. Furthermore, as an object lesson in road building, it might be possible to have specimens in the shape of small roads, or a road running around the border of the village park, so constructed as to illustrate the various types of road building best adapted to the region, using only the materials at hand for their construction and thus showing the extent of the local resources. The tract could also be fenced with various forms of fencing, from the most inexpensive to the more costly, so as to lend variety to the fenced-in sections, and at the same time educate the people, from childhood up, in the best and simplest forms of making a fence. If the reservations should be situated at county lines, or even village lines, pillars of history could be erected, stating the history of the place as briefly as possible. This would not only serve to educate those who live in the various communities, but those who pass through could not fail to find interest in noting facts that are often either forgotten or ignored. Incidentally, if all these suggestions are acted upon, the land and taxable value will be increased.

Last but not least, if there are any water supplies, such as springs and brooks in the vicinity, the proper establishment of water troughs or of fountains along the road would greatly benefit the passer-by as well as the resident, and would frequently help to educate the children as to the importance of conserving a good water supply, a consideration that was fully recognized two thousand years ago in Roman times, and caused the erection of those splendid aqueducts which reflect such credit upon ancient Roman civilization.

HON. GEORGE W. KOINER, MEMBER OF THE VIRGINIA STATE CONSERVATION COMMISSION AND STATE COMMISSIONER OF AGRICULTURE.

Mr. KOINER. I present here the statement promised by Mr. Rosewell Page in his address as the representative of the governor of Virginia.[a]

The area of Virginia is 40,125 square miles (27,168,000 acres), of which 2,325 square miles are water. Its greatest dimensions are from the Atlantic southwesterly to Kentucky, 476 miles; the longest line north and south is 192 miles. The boundary lines of the State aggregate about 1,400 miles.

The estimated population in 1908 is 2,253,284, an increase of 5.3 per cent over that of 1900. In 1906 the estimated population of the leading cities was: Richmond, 87,246; Norfolk, 66,931; Newport News, 28,749; Lynchburg, 22,850. The colored population of Virginia has for years been rapidly decreasing owing to migrations of negroes to the north and to the south. In 1900 the foreign population was only 19,461.

The surface of the State is diversified, rising in a series of six terraces from the southeast to the northwest. The tidewater Virginia is penetrated by the Chesapeake Bay, and has a shore line of 1,500 miles. The middle section of the State is an undulating plain with an elevation of from 200 to 600 feet and extends to the foothills of the Appalachian Range. The western part of the State is mountainous, the Blue Ridge and the Piedmont ranges crossing the State in a southwesterly direction, and the Alleghanys forming the boundary line of West Virginia. The valley section is a broad belt of rolling country, diversified by hills, ridges, and river valleys, lying between the Blue Ridge and the Alleghany Mountains. This region contains the sources of the Shenandoah, Roanoke, James, Kanawha, and Holston rivers. The most important rivers are the Potomac, separating Virginia from Maryland, navigable as far as Washington, and the James, with its extensive network of tributaries, navigable to Richmond. Both of these rivers empty into Chesapeake Bay, as do the York River and the Rappahannock. Along the mouths of these rivers and large portions of the bay are the State's priceless oysterlands. About the heads of these streams is her wealth of forest and water power. Lake Drummond, in the Dismal Swamp, is the only lake in the State.

Archean granites, syenites, metamorphic rocks of a greenish hue, and gneiss form the oldest geological deposits in Virginia. These stratifications are found in the Piedmont plain. The coastal plain to the eastward shows Tertiary and Quaternary deposits, indicated by the presence of sand, gravel, and clay. Coal deposits in several counties of the State, located east of the Piedmont plain, are Triassic in origin. Paleozoic strata predominate in the Appalachian plateau. Cambrian deposits are found in the Blue Ridge. Devonian sandstones and limestones appear in other ranges. The valleys of Virginia are paved with limestone of the Silurian system. Conspicuous among the remarkable geological features of the State are the Natural Bridge, the caverns of Luray, and Weyers Cave.

---

[a] Page 196.

The following mineral products are found in Virginia: Asbestos, barytes, clay, coal, cobalt, copper, gold, granite, graphite, gypsum, iron, kaolin, limestone, manganite, marble, marl, mica, mineral waters, nickel, ocher, pyrites, salt, sandstone, and zinc. The most important are coal, iron, granite, clay, and mineral waters. The bituminous coal output of Virginia in 1904 exceeded 3,500,000 tons. Coal mining at present is chiefly carried on in Tazewell, Buchanan, Dickenson, and Wise counties. The State's product of brown hematite iron ore in 1904 exceeded 500,000 long tons. Iron ore is plentiful in the Piedmont and Appalachian regions. The value of the granite output in 1904 exceeded $500,000; limestone, $400,000. The building stone deposits are widely distributed. The value of clay products in brick and tile in 1904 exceeded $1,500,000. Manganese is found in the Shenandoah Valley. Gold is mined in Louisa and Spottsylvania counties. Saltville is the center of the salt producing industry. The annual output of coke is 700,000 tons; Portland cement, 60,000 barrels; gypsum, 12,000 short tons; mineral waters, 1,000,000 gallons; slate value, $200,000. The total mineral output for 1908 was about $35,000,000.

East of the Blue Ridge the climate is mild or temperately warm, with mean temperature in January of 37° and 77° in July. In winter the minimum temperature seldom exceeds 10°; the maximum in summer is 102°, but generally about 100°. The climate is dry and salubrious. The summers west of the Blue Ridge are cool, and the winter, particularly in the mountains, cold, the temperature falling, as at Staunton, in the great valley, to 8° below zero. The rainfall is evenly distributed and sufficient for agriculture. In the central portion the average is 48 inches; in the great valley it is 38 inches.

In tidewater Virginia the soil is light alluvial, but the mildness of the climate favors garden farming, which is largely followed. Middle Virginia has a subsoil of dark red or yellow clay with rich loams, and along the streams decomposed rock. In the Piedmont division the soils of decomposed sandstone are more fertile than the yellow and grayish soil. The Blue Ridge region has a soil like that in the Piedmont region, but richer in decomposed rock, and particularly adapted to the culture of rich grasses, vines, and fruits. The limestone soils of the great valley produce large crops of grain and grass.

Virginia has great forests with a variety of timber, including pine, oak, hickory, elm, poplar, willow, beech, birch, walnut, maple, cedar, mulberry, locust, sycamore, juniper, cypress, chestnut, etc.

The farm area of Virginia is about 19,907,883 acres, of which about 9,900,000 acres are improved. The following figures show the yield in 1908: Corn, $30,000,000; wheat, $8,000,000; oats, $1,500,000; hay, $10,000,000; tobacco, $8,000,000; potatoes $3,200,000; peanuts, $2,500,000; all trucks, $12,500,000; orchard fruit, $5,000,000; dairy products, $7,000,000; forest products, $10,000,000; miscellaneous crops, $1,300,000; live stock, $70,000,000; total $204,000,000.

The church denominations are: Methodist, Baptist, Presbyterian, Episcopal, Disciples of Christ, Lutheran, Roman Catholic, Dunkards.

The present school system of Virginia, begun in 1870, is under the supervision of a superintendent of public instruction, chosen by the general assembly and the board of education. Separate schools are provided for white and colored children. In 1908 the number of schools were 9,382; pupils, 375,878; teachers, 9,468. Number of state normal schools, 5; high schools with special normal departments, 20; state agricultural colleges, 2; high schools with special agricultural departments, 10. The state and local appropriations for public free schools were $3,519,739.57. Three normal schools for young women, viz: State Female and Normal School, Farmville; State Normal and Industrial School for Women, Fredericksburg; and State Normal and Industrial School for Women, Harrisonburg, Va.

William and Mary College, Williamsburg, founded in 1693, with 20 instructors, 225 students, and 15,000 volumes in library; Washington and Lee University, Lexington, founded 1749, 31 instructors, 500 students, 50,000 volumes in library; University of Virginia, Charlottesville, founded 1819, 83 instructors, 750 students, and 60,000 volumes in library; the Virginia Polytechnic Institute at Blacksburg, and the Virginia Military Institute at Lexington, are great institutions where work of the highest value is being done.

Other colleges are Richmond, at Richmond; Randolph-Macon, at Ashland; Roanoke, at Salem; Virginia Union University, Richmond; Emory and Henry, at Emory; Bridgewater, at Bridgewater; Hampden-Sydney, at Hampden-Sydney; and Fredericksburg, at Fredericksburg. There are women's colleges of high order in Richmond, Lynchburg, and Danville.

The CHAIRMAN. Gentlemen, I desire to express my most heartfelt thanks to all of you who have formed this great movement. Whatever happens here in Washington is of small account unless it is the expression of what happens away from Washington. The center of this conservation movement, in the sense of the active center, is not here in Washington at all, but is scattered all over the country. I want you to appreciate that that is the feeling here. We who are at work under the National Government understand fully that nothing we do is of any consequence except as it meets with the approval of the States and the organizations and citizens of the United States, and just so long as the interest grows and the activity continues in other parts of the country, just so long will the movement succeed, and not otherwise.

Cooperation was the keynote of this meeting, cooperation between the States and the nation, between the States themselves, between the States and the great national organizations, and if this meeting succeeds in establishing, as, since these resolutions passed, I hope and believe it will, a coordinated effort, including all these agencies, directed to one great end, the conservation of our natural resources, it will have done more by itself than all the other things that have ever happened in this movement up to this time. When we get together effectively we shall get together to win. Until we get together effectively, whatever agitation we may have, whatever education we may carry out, will not be brought to the point of action. It is the getting-together side of this movement that impresses me so tremendously at this congress.

Finally, I want to thank you for myself for your kindness to me. I have never supposed that any such kindness as has been exhibited to me during the last two or three days would ever come to my lot. It has come, and I am glad of it, and proud of it. I want every one of you to come to-night to 1615 Rhode Island avenue and see the reason for it—my mother.

Senator **SMOOT**. Mr. Chairman, I believe it would be a good thing to call the attention of the governors here to-day to the fact that there is one class of men which ought to receive our most hearty thanks, for it was that class of men that made it possible to have this inventory taken so completely as it is. They have worked early and late. This work has been done outside of hours with no pay whatever for it, and it would have cost at least half a million dollars if the services had been paid for; not only would it have cost that, but it would have been absolutely impossible to have it within two or three years' time if it had been gathered through any other channel or by any other men.

Mr. Chairman, I wish to offer this motion, that this conference give its most hearty thanks and appreciation to the secretaries of all four of the divisions of the National Conservation Commission, and also to the experts who have worked so hard from all the departments of this Government.

(The motion was unanimously adopted.)

ADJOURNMENT.

The **CHAIRMAN**. Is there any further business to come before this meeting?

Governor **ANSELL**. Mr. Chairman, I move that we do now adjourn sine die.

(Motion carried.)

(Thereupon the joint conference adjourned sine die.)

REPORT OF THE NATIONAL CONSERVATION COMMISSION

WITH ACCOMPANYING PAPERS

FEBRUARY
1909

SPECIAL MESSAGE FROM THE
PRESIDENT OF THE UNITED STATES
TRANSMITTING A REPORT OF THE
NATIONAL CONSERVATION COMMISSION, WITH ACCOMPANYING PAPERS

IN THREE VOLUMES

VOLUME II

EDITED UNDER THE DIRECTION OF THE EXECUTIVE
COMMITTEE BY HENRY GANNETT

WASHINGTON
GOVERNMENT PRINTING OFFICE
1909

HC10
A4
v.2

SENATE OF THE UNITED STATES,
February 18, 1909.

Resolved, That the special message from the President of the United States, transmitting a report of the National Conservation Commission, with accompanying papers and illustrations, be printed in full as a document, taking number 676 of the present Congress, the number of the document containing the special message of the President transmitting this report.

TABLE OF CONTENTS.

Prefatory note 5
Estimates of future population, by Henry Gannett 7
Distribution of rainfall, by Henry Gannett 10
Transportation by water, by Herbert Knox Smith:
  Part I. General conditions 13
  Part II. Water-borne traffic 28
  Part III. Port terminals 44
  Part IV. Rail rates and water rates 50
Growth of internal and foreign commerce, by O. P. Austin 57
Irrigation, by Frederick H. Newell 59
Irrigation, by Samuel Fortier 67
Irrigation laws and organizations, by R. P. Teele 74
Underground waters, by W. C. Mendenhall 86
Floods, by M. O. Leighton 95
Relation of surface conditions to stream flow, by William L. Hall and Hu Maxwell 112
Denudation, by R. B. Dole and H. Stabler 126
Developed water powers, by M. O. Leighton 141
Undeveloped water powers, by M. O. Leighton 159
Concentration of ownership of water powers, by Herbert Knox Smith 171
Control of catchment areas, by Horatio N. Parker 178
Original forests, by R. S. Kellogg 179
Standing timber in wood lots, by Wesley Bradfield 181
Stand of timber, by Herbert Knox Smith 188
Standing timber owned by the States, by J. Girvin Peters 191
Standing timber in possession of the Federal Government, by G. M. Homans. 192
Forest products, by R. S. Kellogg 196
Rate of forest growth, by E. A. Ziegler 203
  approximate rates of growth for different forests 205
  time required to produce various wood crops 214
  acre yields 216
  present average production and total production 219
  Appendix—rates of growth of individual species 223
Methods of increasing forest productivity, by E. E. Carter 270
Foreign sources of timber supply, by Raphael Zon:
  Part I. The forest resources of the world 280
  Part II. How far can we count on foreign sources of supply 351
  references 369
Cost of forestry in different countries, by H. S. Graves 371
Extent to which foreign methods of administration are suited to conditions in the United States, by S. T. Dana 375
Forest fires, by Clyde Leavitt 390
  damage 394
  causes 414
  prevention and control 418
  results accomplished 438
Waste and reduction of timber supplies caused by insects, by A. D. Hopkins. 469

ACCOMPANYING PAPERS

WATERS AND FORESTS

PREFATORY NOTE.

The following papers were prepared by the experts under whose names they appear and who assisted the commission in its labors. These papers form the body of information on which the report of the commission is based and from which the statements of the secretaries have in the main been prepared.

Naturally, these papers, representing as they do the original work of experts along various lines pertaining to the resources of the country, express some diversity in views. Since each opinion is that of an expert, the commission has not deemed it wise to undertake either acceptance or elimination of the views; and has decided, without expressing its own opinion, to leave the experts' views to the test of time as our knowledge extends and becomes more definite.

ESTIMATES OF FUTURE POPULATION.

By Henry Gannett,
United States Geological Survey.

Under normal conditions, the rate of increase of a body of population slowly decreases. Other things being equal, as the density of population increases and as the difficulty of breadwinning becomes greater with diminished opportunity, natural increase and immigration decrease. The rate of increase may, and frequently has been, affected by disturbing factors, causing it to increase temporarily or to decrease more rapidly than normal. As an illustration, the population, increase in numbers, and rates of increase in the United States by decades from 1790 to 1900 are given in the following table:

Year.	Population.	Increase.	Rate of increase.
			Per cent.
1790	3,929,000		
1800	5,308,000	1,379,000	35
1810	7,240,000	1,931,000	36
1820	9,638,000	2,399,000	33
1830	12,866,000	3,228,000	33
1840	17,069,000	4,203,000	33
1850	23,192,000	6,122,000	36
1860	31,443,000	8,251,000	36
1870	38,558,000	7,115,000	23
1880	50,156,000	11,597,000	30
1890	62,622,000	12,466,000	25
1900	75,569,000	12,946,000	21

From 1780 to 1840 the population was little disturbed and immigration was small, and the rate of increase dropped from 35 or 36 per cent to 33 per cent. Between 1840 and 1850 there was a great wave of immigration, which increased in the succeeding decade and raised the rate of increase to 36 per cent. Then came the blighting effects of the civil war; deaths from casualty and diseases and the reduction of births (aided to an uncertain extent by omissions in the census of 1870) reduced the rate in that decade to 23 per cent. Between 1870 and 1880 the country began to recover from the effects of war, and the rate of population increased to 30 per cent. The succeeding decade witnessed a drop of 5 per cent, and the following one of 4 per cent. Thus in 110 years the rate of increase of population has been reduced from 35 to 21 per cent. If normal conditions prevail in the future, it is certain that the rate of increase will continue to diminish until the rate reaches that of the densely populated countries of western Europe—about 10 per cent increase per decade. It will be noted that in the table the numerical increase has been steady excepting for the period between 1860 and 1870.

A great variety of population conditions exists in the United States. There are communities where increase is supplied wholly by immigration; others receive no immigration, but are dependent upon the excess of births over deaths; there are regions where commerce and manufacturing cause dense population; thickly populated farming regions now passing into manufacturing communities; prosperous farming regions; sparsely peopled pastoral lands; and desert wastes with few people. All have different rates of increase, and the figures discussed represent the total of all these different conditions.

Several predictions of our population have been made at various times by different and by more or less complicated and elaborate methods. One or two of these predictions have by accident hit very near the truth, as made known by later censuses, but all have been finally wide of the mark.

A mathematical method which has been employed consists in deducing the equation of the curve which the population has made, beginning with the first census and ending with the latest available, and so projecting this curve into the future. Such a formula expresses past conditions with accuracy, but its application to the future assumes that similar conditions will prevail hereafter, which is extremely unlikely.

A simple method which has been employed is to assume that the numerical increase of each decade will continue the same and be equal to that of the latest decade measured by the census, at present that of 1890 to 1900, when the increase was 13,000,000. It is not probable, however, that the numerical increase will remain stationary, but will increase still more. Great Britain, with 347 inhabitants to a square mile, shows a continual increase in its decennial increment, and other densely populated European countries show the same. Hence, it is believed that such predictions are somewhat too small.

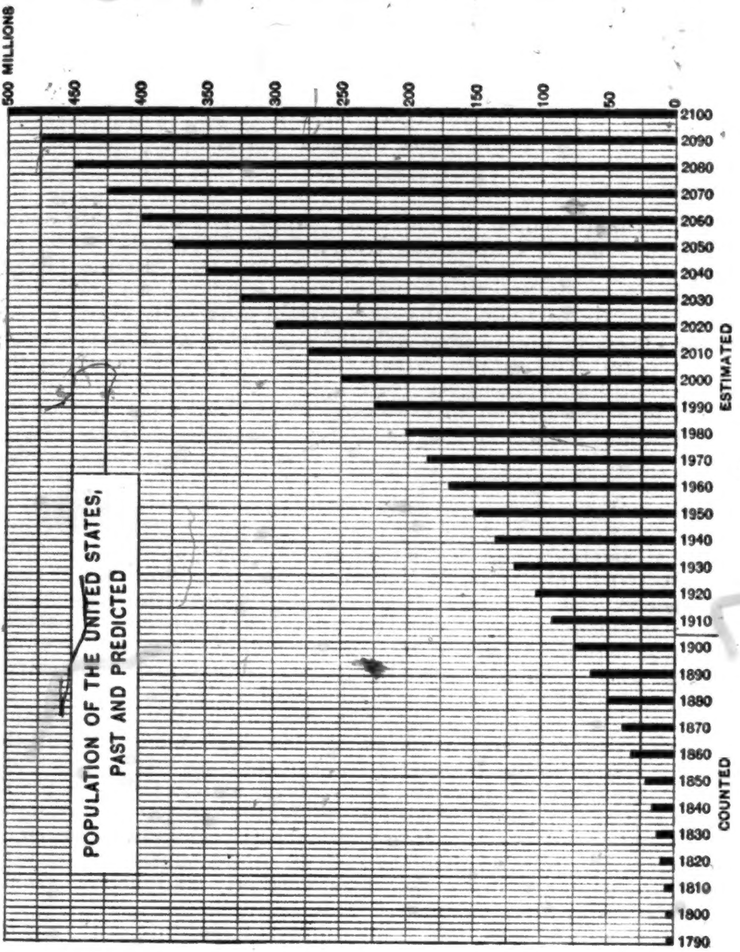
Another simple method assumes that the rate of increase, which was 21 per cent from 1890 to 1900, will decrease by a certain per cent each decade, say 1 per cent, being 20 per cent between 1900 and 1910, etc.

It is probable that for several decades the amount of reduction in the rate of increase will be greater than 1 per cent, and that then the rate of its reduction will be slowly lessened, so that perhaps a century hence, in the year 2000, the rate of increase may be 10 or 11 per cent, but the population will not be as great. As a guess, the population in 2000 may be placed at a figure not very far from 250,000,000, or about midway between the results given by these two methods.

Accepting the above figures, the following table shows by decades the probable population and rates of increase until the year 2000, with the guess extended a century further into the future:

Year.	Population.	Increase.	Year.	Population.	Increase.
		Per cent.			*Per cent.*
1900	76,000,000		2010	274,000,000	10
1910	90,000,000	21	2020	299,000,000	9
1920	104,000,000	16	2030	325,000,000	9
1930	119,000,000	14	2040	350,000,000	8
1940	134,000,000	13	2050	375,000,000	7
1950	150,000,000	12	2060	400,000,000	7
1960	167,000,000	10	2070	425,000,000	6
1970	184,000,000	10	2080	450,000,000	6
1980	202,000,000	10	2090	475,000,000	5
1990	225,000,000	11	2100	500,000,000	5
2000	249,000,000	11			

Thirteen countries of Europe, including all the larger, older, and most densely settled ones, which comprise collectively a population of 260,000,000, show a decennial increase of population in the last decade of 24,400,000. Here is a case approaching parallelism with what the United States may expect to be ninety or one hundred years hence.



DISTRIBUTION OF RAINFALL.

By **Henry Gannett**,
United States Geological Survey.

The ultimate source of our water supply is rainfall, the chief source of which is evaporation from the Pacific Ocean, while secondary sources are the Gulf of Mexico and the Atlantic Ocean. Brought from the Pacific by the westerly winds of the north temperate zone, the moisture in the air is carried eastwardly nearly across the continent in diminishing quantities, varying at different times of the year. The supply in the atmosphere is reenforced in the Mississippi Valley from the Gulf of Mexico, whence it is drawn inland by southerly and southwesterly winds; and again east of the Appalachian Mountains it is reenforced from the Atlantic Ocean, from which it is drawn by easterly winds accompanying cyclonic disturbances.

The areal distribution of the rainfall is in general terms as follows: The precipitation is very heavy upon the north Pacific coast, where at several points in the States of Washington and Oregon it exceeds 100 inches annually, but diminishes southward so that at San Diego, Cal., the rainfall is very light and desert conditions prevail. Inland, back of the Coast Ranges, the northern part of the great depression separating these mountains from the Cascades and the Sierra Nevada is well watered. The amount of rainfall diminishes southward, so that in the southern part of the depression, which is occupied by the San Joaquin Valley, precipitation is scanty and arid conditions exist. The high mountains of the Cascade Range and of the Sierra Nevada are copiously watered, but east of them, in the valleys and low plateaus and on the great plains as far east as the one hundredth meridian, the rainfall is very light. The mountains of this (the Rocky Mountain) region, however, enjoy a more copious rainfall than the valleys, the amount differing with the altitude and latitude, the more northerly and higher ranges receiving the greater amount.

Continuing eastward, the small supply of moisture still remaining from that brought from the Pacific Ocean is augmented by a generous contribution from the Gulf of Mexico, and the rainfall increases. Upon much of the Gulf coast it exceeds 60 inches annually, but it diminishes northward, until in the neighborhood of the Great Lakes the precipitation does not exceed 30 inches yearly. The Appalachian Mountains are abundantly watered, and the Atlantic plain receives everywhere a sufficiency for agricultural purposes, derived largely from the Atlantic Ocean.

The causes of these great differences in amounts of precipitation in the various parts of the country are simply explained. All air holds a certain amount of moisture, ranging from the amount sufficient to saturate it to a very small proportion of that quantity. The point of saturation is much higher in warm air than in cold air; i. e., warm air can hold a much larger quantity of moisture than can cold air. Whenever air is cooled below the point of saturation, rain falls, and it can only fall when thus chilled. There are several ways in which air currents may be cooled; the current may be forced upward, as when it climbs the slope of a mountain range; it may be cooled by intermingling with colder air currents; and again, by coming in contact with a cold land.

The sea receives heat slowly and parts with it slowly; the land, on the contrary, is rapidly heated and parts with its heat as quickly. It results from these conditions that the ocean has a fairly uniform temperature the year around, while the land is much colder in winter than in summer.

Now, let us apply these principles to the United States. The prevailing winds in the Temperate Zone are from the west. These winds come off the Pacific laden with moisture and having the temperature of the ocean. If they encounter land having a lower temperature they are chilled below the point of saturation and some of the moisture is deposited in the form of rain or snow. If, on the other hand, the land is warmer than the air, the currents pass over it without any reduction in temperature and with little or no loss of moisture.

During the winter the north Pacific coast is colder than the sea, and hence the copious precipitation which it enjoys at that season of the year. In the summer the conditions are reversed, and the air currents, although containing at least as much moisture as in cold weather, pass over the land with comparatively little loss from precipitation. Southward, down the coast, the land is progressively warmer in winter, and consequently receives less rain, while in southern California there is little rain even in winter, except upon the mountains. Although the atmosphere at Los Angeles contains more moisture than does that at Washington, D. C., rain seldom falls in the former locality, as there is nothing to cool the air currents.

Thus it is that the Pacific coast has well-defined wet and dry seasons corresponding to winter and summer in other parts of the country. In winter the country drains the air currents of their moisture and they pass eastward as dry winds, while in summer these currents carry most of their moisture over the mountains and precipitate it upon the Rocky Mountains farther to the east and upon the great plains. Hence, it is that in these two regions the greater part of the year's rainfall occurs in the warmer half of the year.

Going eastward into the Mississippi Valley the moist air currents, drawn northward from the Gulf of Mexico by southerly winds, are carried progressively into more northerly and colder climates, and part of their moisture is deposited in a similar manner.

The Weather Bureau has furnished the Commission with data upon precipitation from about 4,000 stations within the limits of the United States proper. These data consist of records of the normal yearly and monthly rainfall, and the study which has been made of them is very illuminating.

For the preparation of a rainfall map, the data from all these stations were platted upon a large-scale map of the United States, and in the plains and level country generally isohyetal lines were sketched at intervals of 10 inches of rainfall in accordance with these data. In the mountain regions, however, but little weight was given to the rainfall data, inasmuch as the stations are generally situated in the canyons rather than on the ridges, and hence do not represent well the rainfall of the region, but in such country consideration was given to the relief of the land, its mountains, etc., and to the character of its vegetation; it is known, for instance, that the lower limit of yellow pine timber is not far from the isohyetal line of 20 inches. The areas between these isohyetal lines were measured by planimeter, and the average rainfall of each such area was assumed to be the mean of the two isohyetal lines limiting it. The areas were then multiplied by their average rainfall, the products summed up, and the total divided by the total area of the country. In this way the figure, 29.4 inches, was obtained as the mean average rainfall of the United States.

Another use has been made of these data. The percentage of the annual rainfall which was received during the six warmer months was computed for each station, and the results platted upon a map, which thus shows the preponderance of summer or winter rainfall throughout the country. Over most of the area the greater part of the rain occurs in the warmer season, but upon the Pacific coast and in the Rocky Mountains as far east as western Montana, eastern Idaho, eastern Utah, and Arizona the bulk of the precipitation comes in the colder season. The highest proportion, three-fourths to four-fifths of that of the year, is on or near the Pacific coast, and the proportion diminishes eastward. Again, in an area adjacent to the Gulf of Mexico, winter rainfall preponderates slightly. The highest proportional summer rainfall is on the plains east of the Rocky Mountains, where it ranges from three-fourths to four-fifths of that of the year. In the Mississippi Valley and on the Atlantic plain the proportion which falls in the warmer season is but little more than half of the annual precipitation.

TRANSPORTATION BY WATER.

By Herbert Knox Smith,
Commissioner of Corporations.

Part I.—GENERAL CONDITIONS OF TRANSPORTATION BY WATER.

The first part of this discussion on Transportation by Water in the United States deals with the general conditions of such transportation, involving the following topics:

(1) The natural and artificial coastwise and inland waterways, and the character and results of the more important improvements thereof.

(2) Vessel equipment, types, and number and tonnage.

(3) Vessel ownership, business organization, and finances of navigation lines and companies, in regular lines, bulk carriers, and towing concerns.

(4) Contracts for the carriage of goods, shipping documents, the liability of carriers, and statutes relating thereto.

(5) Marine insurance and its general influence on water transportation.

(6) Taxation of vessels and of navigation companies.

The present Part I is of a somewhat preliminary nature. It sets forth mainly conditions familiar to those in the business, though not hitherto presented to the public in complete form. Such a survey of conditions is necessary as a preparation for the discussion of the specific branches of the subject in subsequent parts of this report.

This report deals only with domestic traffic, except so far as foreign traffic is incidentally involved in such discussion. The domestic water-borne traffic carried by vessels of the United States is far larger than the foreign trade so carried, and of much greater importance. Coastwise traffic is by law restricted to American vessels. Most of the foreign trade is carried in foreign vessels. Domestic coastwise commerce, however, uses the same ports as does the foreign commerce, and the early policy of the Government in improving these ports, with especial view to foreign trade, gave also especial advantage to coastwise trade. In physical characteristics also the coastwise business is of the same class as foreign business, while the two differ largely from inland water traffic.

WATERWAYS AND THEIR IMPROVEMENT.

Interstate commerce moves on natural and artificial waterways. The former embrace the Atlantic and Pacific coasts and the Gulf of Mexico, the Great Lakes, and numerous navigable streams. These natural waterways have been greatly improved. Artificial waterways are government, state, and private canals.

COAST LINE.

The Atlantic coast line of the United States is more than 2,000 miles in length, and it is extended for another 1,900 miles by the Gulf of Mexico. The Pacific coast line is more than 1,800 miles long. The total coast line of the United States aggregates 5,700 miles. This is increased to a meandered length of 64,604 miles by including the numerous indentations, many of which provide important bay, sound, and inlet routes. Chief of these are the Gulf of Maine (so-called), Long Island Sound, Delaware Bay, and Chesapeake Bay, on the Atlantic coast, and Puget Sound, on the Pacific coast.

GREAT LAKES.

Next in significance are the Great Lakes, the most important group of inland waterways in the world. Their shore line in the United States territory is 2,760 geographical miles. The meandered length is 4,329 miles. They are connected by a series of natural and artificial channels. Canals also connect the Lakes with the Atlantic Ocean and the Mississippi and Ohio rivers, but these are not of dimensions to permit of through navigation by large vessels. Another series of canals, constructed by the Canadian government along the St. Lawrence River, give 14 feet draft to Montreal, and are used to some extent by American vessels.

On the coasts the Government has deepened harbors and connecting channels. Similar works on the Great Lakes give a depth of 20 feet on the main channels.

COAST AND LAKE ROUTES.

The coastwise trade routes radiate mainly from a few central ports, such as Boston, New York, Philadelphia, and Baltimore, on the Atlantic coast, and San Francisco, Portland, and Seattle, on the Pacific. On the Lakes, notwithstanding the large number of routes, the great movement of traffic follows a few well-defined main lines. Most important is the route from Lake Superior ports through Lake Huron to Lake Erie ports. Another main route, formerly the most important, is that from Lake Michigan ports to ports on Lake Erie.

RIVERS.

The number of navigable streams used to a considerable extent for commercial purposes in the United States is about 295, with an approximate mileage of 26,400.

Number and mileage of navigable streams in the United States, by districts.[a]

	Streams.	Navigable length.		Streams.	Navigable length.
		Miles.			*Miles.*
Tributary to the Atlantic	148	5,365	Flowing into Canada	2	315
Tributary to the Gulf, exclusive of the Mississippi and tributaries	53	5,212	Tributary to the Pacific	38	1,606
Mississippi River and tributaries	54	13,912	Total	287	26,410

[a] No classification of this sort can, of course, be absolutely accurate. Sections of a river that might be rendered navigable are not included, nor streams practically abandoned for navigation purposes. There are also many small streams navigable for very light vessels in local commerce which have not been included.

The chief of these are:

Navigable lengths and depths of principal rivers of the United States.

[e] 20 feet to Jacksonville, 5 feet to Sanford.
[f] 20 feet to Vancouver, Wash., and Portland, Oreg., 8 feet to The Dalles.

LACK OF UNITY IN WATER SYSTEM.

The streams tributary to the Atlantic do not form connected systems, but often form extensions of coastwise routes into the interior. Streams tributary to the Gulf are more often connected with each other, foremost being those of the Mississippi Valley system, which aggregate about 14,000 miles. On the Pacific coast there are also several connected systems, such as the rivers leading into Puget Sound, the Columbia River and its tributaries, and the rivers of central California.

Most streams included in the foregoing table are navigable only for light-draft boats. Forty streams have a total of about 2,600 miles of 10-foot navigation, and 70 streams give about 3,200 additional miles of navigation of from 6 to 10 feet during the greater part of the year, a total of about 5,800 miles of river navigation of 6 feet and over. These totals, however, do not of course mean that there are any such continuous stretches of inland waterways of these respective depths. The greater number of these streams flow into the Atlantic, but few of the Atlantic rivers have more than 100 miles of navigation over 6 feet in depth. The longest connected river system is the Mississippi and its principal tributaries, with about 2,500 miles of a depth of 6 feet or more.

It is evident that rivers having a navigable depth of only 6 feet can not be used by vessels suited to ocean or Great Lake navigation, and furthermore, that vessels which give the most economical service on rivers having that depth can not be used on still shallower rivers. These facts, together with the shortness of the navigable length of most rivers having a 6-foot depth and their unconnected character, are of great importance in estimating the present value of our inland waterways. It is evident that these waterways constitute by no means a unified system. The predominating importance of through traffic in modern transportation makes this lack of unity a serious defect, and accounts to a considerable degree for the failure of our waterways to hold their own in competition with the rail system.

CANALS.

About 4,500 miles of canals have been constructed in the United States. Of these, 2,444 miles, costing in all about $80,000,000, have been abandoned.

The height of interest in canal building came about 1827 to 1837, after the success of the Erie Canal. The crisis of 1837 stopped canal building for the time. The introduction of the railroad about this time was also an important factor in this decline. Since then the use of canals has been as a whole steadily decreasing, both in absolute amount and still more markedly in proportion to the total traffic of the country.

This is due in part to improvident original location of the canals, in part to mismanagement and to adverse control of strategic connections and terminals, but above all else to the fundamental inability of the ordinary type of towpath canal to meet modern conditions of transportation. They are thus unable to compete with railroads to any considerable extent.

Notwithstanding these facts, private and State canals still exist. State canals are maintained in New York, Ohio, Illinois, and Louisiana, with a total mileage of nearly 1,360, constructed at a cost estimated at $156,983,538, as follows:

State canals in operation in the United States.

Name and location.	Termini.	Length.	Depth.
		Miles.	*Feet.*
New York:			
Erie	Buffalo and Albany	355.1	7
Champlain	Troy and Whitehall	81.0	5
Oswego	Oswego and Syracuse	38.0	7
Cayuga and Seneca		25.0	7
Ohio:			
Ohio and Erie	Cleveland and Portsmouth	326.0	4
Miami and Erie	Toledo and Cincinnati	269.0	4-6
Illinois and Michigan	Chicago and La Salle	101.9	6
Chicago Sanitary and Ship Canal	Chicago and Lockport	33.0	22
New Basin Canal (Louisiana)	New Orleans	6.7	8

The Ohio and Illinois canals are antiquated waterways, with little traffic; and the Erie Canal, in spite of its important past, is inadequate in its present condition to meet modern traffic demands, although the new barge canal in course of construction by the State of New York is intended to give a revival of this route.

There are 16 private canals in operation in the United States of more than local importance, with an aggregate mileage of 632, as follows:

Private canals in operation in the United States.

Name of canal.	Termini.	Length.	Depth.
		Miles.	*Feet.*
Delaware and Raritan	New Brunswick and Bordentown	66.0	8-9
Morris	Philipsburg and Jersey City	106.7	5
Lehigh	Coalport and Easton	48.0	6
Delaware Division	Easton and Bristol	60.0	6
Schuylkill Navigation		90.0	6½
Chesapeake and Delaware		13.6	10
Chesapeake and Ohio	Cumberland and Georgetown	185.0	6-7
Dismal Swamp		22.1	9
Albemarle and Chesapeake		11.0	9
Fairfield (North Carolina)		4.0	6
Newbern and Beaufort (North Carolina)		3.2	5
Old Basin (Louisiana)		2.5	7
Barataria and Lafourche (Louisiana)		7.0	6
Harvey's (Louisiana)		5.35	6
Lake Borgne (Louisiana)		7.0	7
Willamette Falls (Oregon)		.6	6

The capital stock reported by 8 companies owning these canals is $43,326,539. Their total indebtedness as reported to the Bureau is $38,307,740. The more important private canals are those comprising the Atlantic coast system, which connect natural waterways so as to furnish continuous inland communication for light-draft vessels from the sounds of North Carolina to Long Island Sound, though their use for such long-distance traffic is wholly insignificant. Most of these canals have a declining traffic. Little has been done in the way of improving them since the civil war; and several have come into the possession or control of railroads, which appear to discourage their use. The control of canals by private interests does not appear to be successful. Such private control also to some extent impedes free use of the natural waterways with which they are connected.

The "towpath canal," forming a route in itself, and not a mere short connecting link or extension of deep open routes, is wholly outclassed in attempting to meet the demands of modern transportation. Using animal power, they are too slow for most high-grade traffic. The depth of water seldom exceeds 7 feet, so only small boats can be used. Moreover, it is unable to furnish feeder lines, factory sidings, etc., with the ease of the rail system. The bulk of our traffic is now so largely long-distance that even the longest canal can not depend on traffic wholly originating and terminating within its limits; and when it thus has also to seek long-distance traffic, for which it is merely one link in the chain, it meets heavy rail competition, difficulties of transshipment, and difficulties of connecting terminals. This struggle is so keen that the slightest original disadvantage may easily determine the issue.

The question as to the value of a canal for steam-towed barges of 1,000 to 1,500 tons is still to be determined by practical use.

WATERWAY POSSIBILITIES AND LIMITATIONS.

At first glance the possibilities of our present natural system, if properly developed, seem great; but any proper plan of development must first consider in detail a number of physical and economic restrictions, which place very decided limits on waterway traffic, especially inland river traffic. Differences in types of waterways are of great importance. The extreme physical differences between deep, open water routes, like the sea or the lakes, and the shallower, winding, and narrow channels of rivers and canals, make the use of the two not at all comparable. Arguments as to one can not be safely based on the facts of the other. A corresponding difference in types of vessels suitable thereto and now used thereon is a natural consequence. These two conditions impose great restrictions on the complete unification of the system, and what may be called the interchangeability of the floating equipment, and consequently on through shipments.

This lack of unity and of interchangeability is a factor of enormous importance in the use and development of waterways and their relations with the railroad system.

GOVERNMENT AND STATE IMPROVEMENTS.

Until about 1850 the improvement of navigable streams and the construction of artificial waterways in the United States were principally carried on by the several States and by private corporations. Both classes of enterprises, however, were sometimes encouraged by the United States Government, either by appropriations or, more frequently by land grants and subscriptions to stock.

Since about 1870, the date of the present form of the river and harbor bill, the policy of the United States Government has undergone a radical change. Many improvements formerly conducted by States and private corporations have been taken over by the Government, and the amounts appropriated for waterway improvements have been largely increased. The total federal appropriations for river improvements and canals (excluding harbor works) to 1907 have been about $250,000,000.

Canals owned by the Government form links in through-water routes, such as the St. Marys Falls Ship Canal, rather than distinct routes in themselves. The improvement of rivers by the Government has consisted in the removal of obstructions to navigation, the deepening of channels, the construction of revetments, and the development of slack-water navigation by the building of locks and dams for the purpose of maintaining a proper depth. Such improvements have been carried out to some extent on most of the navigable streams of the country, the most comprehensive and connected system of river improvement being that of the Mississippi and some of its important tributaries.

COOPERATION IN IMPROVEMENTS.

In the development of our waterway system, while undertaken in part by state and later and more extensively by federal power, there has been very little of that cooperation between central and local authority that appears in the best of the European systems. The United States, the States, the counties, levee districts, and municipalities have all spent large sums of money on waterway improvement, but for the most part separately. There has thus been waste, lack of uniformity, lack of comprehensive plan, and especially a lack of any proportionate contribution from localities peculiarly benefited.

While it is true that the entire country is to some extent interested in a good waterway system in each part thereof, nevertheless it must be remembered, as pointed out above, that any complete unification of that system is, for the present at least, physically impossible, and that therefore the traffic on such waterways will remain for a time confined to certain large sections of the country, and the benefits thereof will also to a considerable degree be local. European countries have in many cases met a similar condition by a distribution of costs of improvements apportioned upon localities in some ratio to special benefits received.

EQUIPMENT EMPLOYED IN TRANSPORTATION BY WATER.

TYPES OF VESSELS.

These include various classes of craft, such as sailing vessels, steam vessels, gasoline boats, barges, and canal boats. Steam vessels show a continuous and rapid increase both in number and tonnage. They have exceeded sailing vessels since 1895 and now have more than double the tonnage. Sailing vessels have declined in importance since 1860. There has also been a notable increase in the number of barges hauled by towboats, especially on the Mississippi and its tributaries and on the Atlantic and Gulf coasts, showing an important change in the form of traffic movement. The total number of unrigged craft in the United States in 1889 was 16,937, as compared with 20,263 in 1906.

Special recent developments in the types of vessels are particularly noticeable in regard to vessels for bulk cargoes. Thus there are the grain and ore bulk carriers on the Great Lakes; steam freighters and coal, fruit, and oil carriers on the Atlantic and Gulf coasts; and steam schooners on the Pacific coast. The competition of such vessels with sailing vessels has, in turn, led to the building of four, five, six, and seven masted schooners. Older sailing vessels are often converted into schooner barges, which are towed from port to port. Gasoline boats are coming into use for local traffic on the rivers of the Mississippi Valley and on the Pacific coast. A type sui generis is the log or lumber raft, notably the huge "cigar rafts" on the Pacific coast.

VESSEL TONNAGE.

The total gross tonnage of documented vessels engaged in the domestic trade in 1896 was 3,858,927 tons, and in 1906, 5,735,483 tons, a gain of 1,876,556 tons, or 48 per cent. The tonnage of American vessels engaged in the foreign trade, after reaching its maximum in 1860, has continued to decline except for a slight increase since 1900. In 1896 it was 884,954 tons, and in 1906, 939,486 tons, an increase of only 94,532 tons, or 11 per cent.

The distribution of domestic vessels by districts in 1907 shows that the Atlantic and Gulf coasts are the most important districts, including nearly half of the total documented tonnage and two-thirds of the sailing-vessel tonnage. The Great Lakes have more than one-third of the total documented tonnage and almost half the total documented steam tonnage of the United States.

There has been a notable increase in the size of vessels on the coasts and the Great Lakes, similar to the increase in the size of railroad rolling stock, and with similar results in the reduction of transportation costs. As a general rule, and with vessels of the same type, the larger the vessel the lower the cost of carriage.

The size of vessels is, however, limited in nearly all cases by the depth of channels and harbors and by the terminal accommodations. Though the limits vary widely on different classes of waters and at different ports and channels, it may be said in general that a great many vessels have already been built with as great draft as the waterways they use will permit, and that in the case of most of our rivers and canals the maximum draft of vessels is scarcely sufficient to permit very economical operation. This fact has an important bearing on the possibilities of successful water transportation.

DIVERSITY IN VESSELS.

Reference has already been made to differences in depth of different classes of waterways as requiring differences in the size of vessels. These necessitate transshipment in order to secure through transportation, even between points both of which are on connecting waterways. Other differences in physical conditions of different kinds of waterways also prevent the use of the same vessels for through shipments. Thus vessels used on quiet inland waterways, such as smaller inlets and lakes and on rivers and canals, are neither sufficiently strong nor have they sufficient freeboard to permit them to be used on the Great Lakes or the ocean. Naval architects even assert that were there enough channel depth to take vessels from the Great Lakes to tidewater, nevertheless it would be preferable, and almost necessary, to tranship at tidewater as now. Ore vessels on the Great Lakes, they state, are not in model or in structural strength adapted for ocean conditions.

Again, the narrowness and tortuousness of river channels almost entirely prevent the use of sailing vessels, and practically also prevent the use of large steam vessels such as are adapted to the Great Lakes or the ocean. Thus, even on a channel as deep as the Hudson practically no large ocean boats are seen at any considerable distance above New York, though there is 25 feet depth of water up to Hudson, 100 miles above New York. Owners do not care to risk the dangers of a restricted channel with large ocean-going craft. Again, in the present state of the art, even light-draft screw steamers can not be used to advantage, generally, on the Mississippi at any considerable distance above New Orleans. Aside from the shallow depth, the need for constant backing and turning at the innumerable bends makes the stern-wheel paddle the only generally successful method. The latter, of course, is useless on the open sea.

SPECIALIZATION OF BULK-CARGO VESSELS.

Specialization in vessels is not only with respect to the peculiar condition of the waterways, but it has gone further in adapting them to the peculiar conditions of the different kinds of traffic. This adaptation is especially conspicuous in what are known as bulk-cargo vessels; that is, vessels which do not carry package freight, or diversified freight, but which carry one or at most a few kinds of articles in bulk. Thus on the Great Lakes bulk steam vessels for ore or coal, and others for grain, are used to an enormous extent. On the Atlantic and Gulf coasts there are bulk vessels for coal, for oil, for fruit, etc. On the Pacific coast a type of steam schooner has been developed, especially intended for hauling lumber in bulk, and special lumber vessels are also used on the Great Lakes and the Atlantic Ocean. On the Ohio and Mississippi bulk coal barges are extensively used, and other bulk boats to some extent. The use of rafts of logs on the Great Lakes, on the rivers, and on the Pacific coast is a special development of bulk transportation.

The great predominance of bulk traffic emphasizes this specialization in vessels. On the Great Lakes steam bulk freighters carry about 80 per cent of the total business. The bulk coal traffic on the Atlantic and lumber traffic in steam schooners on the Pacific represent an important part of the total coastwise commerce. On the rivers of the Mississippi Valley the bulk carriers and rafts handle about three-fourths of the total traffic.

This development of the bulk water carrier is highly significant of the peculiar demands of modern transportation. It has been most successful in those cases where the products to be shipped are either on or very near the water, and where the destinations to be reached are likewise on or near the water. This is conspicuous, for example, in the case of the coal carried on the Monongahela, Ohio, and Mississippi rivers, most of which is produced at or very near the rivers. At the same time a large part of the traffic in bulk water carriers reaches those carriers only by rail haul, and a considerable part is delivered by rail to the final destination. This occurs, as on the Lakes, where there is a large uniform supply, a corresponding demand, and a proportionately long water haul connecting the two.

This specialization of types of vessels, as in the various classes of bulk freighters, in the use of gasoline launches on the Mississippi River, etc., indicates the struggle of a system to adapt itself to its conditions. Probably had there been no rail competition, that adaptation would have gone much farther and would have approached something like a good operating system, even on the inferior waterways, such as rivers and canals. But in the keen struggle with the railroad for existence, hand-to-mouth methods have been necessary, except on the Great Lakes and the coast, and even there it is to some extent hampered by rail competition. Could the rail and water systems have cooperated instead of competing, it seems probable that a reasonable share of traffic would have produced a modern system of waterways transportation even on our smaller rivers.

From these considerations as to the character of our waterways, and of the vessels used upon them, it is obvious, as already stated, that our inland waterways are far from constituting a unified system, and that, save on the Great Lakes and in the coal traffic on the Ohio, they are very inferior in efficiency to railroads. In a later part it will be shown that the traffic on rivers and canals of the United States is insignificant in comparison with the rail traffic, or with traffic on the Great Lakes and the coasts. Diversity in water-route and channel conditions, diversity in vessel types, in motive power, and in terminals, as well as in carriers' liability, insurance, freight classification, and traffic contracts generally, have resulted in extreme absence of organization of our water system as a whole. It is thus helpless in competing for long-distance traffic with a modern, unified, standardized system like that of the railroads.

LIMITATIONS OF TRANSSHIPMENT.

It can not be expected that any reasonable expenditure on our inland waterways will wholly remove these difficulties. It would never pay, except in a few cases, to try so to deepen and improve the rivers and canals as to permit vessels suited to the ocean to use them to any appreciable extent. Transshipment from one water carrier to another will continue to be necessary on most long inland, or partly inland, hauls, even from and to points actually on waterways. Moreover, the greater part of our traffic originates in, or is destined to, points not on waterways, so that transshipment from rail to water will always be necessary on most longer hauls which seek to use the waterways at all.

Since such a large portion of our traffic is long-distance traffic which will thus involve transshipment, the question of the future development of our inland waterways resolves itself into one of relative operating expenses and of investments of capital. There is little doubt that for a given distance a continuous water haul in a boat of even moderate size is, and will continue to be, cheaper in operating costs alone than a similar continuous rail haul. If the channels are made deep enough to permit the use of relatively large boats, this greater cheapness will, in some cases, probably be sufficient to cover also the additional cost of transshipment. The question is, however, whether besides doing so it will afford enough saving to cover reasonable interest on the investment in waterways and water terminals necessary to secure such measure of efficiency. This is a question which can only be answered after most exhaustive engineering estimates of the cost of constructing waterways of different depths and most thorough investigations of operating expenses of different kinds and sizes of vessels, in comparison with expenses of rail transportation.

It should be noted, however, in considering how far expenditures of capital for improved water routes are advisable, that in some cases the railroads have already reached the limit of their carrying capacity and that they will have to make additional investments of capital if they are to meet the demands of transportation. The relative amount of investment necessary thus to increase the facilities of the railroads, as compared with the investment necessary to afford adequate water routes and terminals, must therefore likewise be taken into account.

BUSINESS ORGANIZATION AND FINANCES.

OWNERSHIP.

Prior to the development of steam navigation vessels were usually owned and operated by individuals or small groups of individuals. Sailing vessels are even now more commonly thus owned than by corporations. The corporate form, however, has gained steadily, at first with steam vessels and later with sailing vessels and barge lines. There was a total of 37,321 vessels, with a total gross tonnage of 12,893,429 tons, and valued at more than $507,000,000, included in the census of 1906. Of these, corporations owned more than one-half of the number, and more than three-fourths of the total tonnage and value. Of steam vessels corporations controlled 42.6 per cent, representing 87.6 per cent of the gross steam tonnage; and of freight and passenger vessels running on regular lines they controlled 56.8 per cent, with 91 per cent of that tonnage. The proportion of vessel tonnage owned by corporations is everywhere larger than the proportion of the number of vessels so owned, indicating that the vessels owned by corporations are usually the larger ones. In 1906 the average size of vessels owned by individuals was 113 tons, of vessels owned by firms 223 tons, and of vessels owned by corporations 526 tons.

Many steamship corporations, however, are essentially private affairs, with few stockholders. They often are controlled by a few individuals, often of the same family. Navigation companies have been in most cases conservatively capitalized and their stock not offered in the open market. But in recent years there have been some notable changes in these respects. By expansion or consolidation there have been developed quite a number of great corporations with large fleets and operating many lines over a wide territory. The most striking instance of consolidation is that of the Consolidated Steamship Lines, commonly known as the Morse combination, including half a dozen important Atlantic coast lines, covering a large share of the regular packet-line business in this important district.

An especial feature has been the recent acquisition and operation of steamer and barge lines by railroad companies and by industrial and trading concerns, including several of the great combinations, such as the United States Steel Corporation, the Standard Oil Company, the Southern Pacific Railroad Company, the New York, New Haven and Hartford Railroad Company, the New York Central Railroad, the Pennsylvania Railroad, and others.

FINANCIAL.

The information available is inadequate for a satisfactory discussion of financial operations. The scope of the data is limited to a few of the most important facts relating to the capital stock (in case of corporations), indebtedness, gross earnings, and operating expenses. But even on these points the failure of many concerns to make any report renders the details incomplete, and only a few general and tentative conclusions can be drawn therefrom.

The information in regard to capital stock and indebtedness is more complete than in regard to earnings and expenses, but even there special difficulties are encountered. Where navigation lines are owned by railroads or industrial corporations there is usually no specific record of the capital invested in the navigation lines as distinguished from the remaining property of the corporation.

The aggregate capital stock of navigation companies reported to the bureau is $248,720,178; the aggregate bonds and other indebtedness is $170,387,005, making a total capitalization of $419,107,183. This is for 366 companies, operating less than half the total vessel tonnage in the United States.

In the information as to earnings and expenses, the utter absence of anything approaching uniformity in the method of accounting makes the returns of limited value. The aggregate gross earnings of concerns reporting earnings and expenses amounted to $81,708,289, and their aggregate operating expenses amounted to $65,816,251, leaving net earnings of $15,892,038. Operating expenses thus averaged 80.6 per cent of the gross earnings, a ratio of operating expenses to gross earnings much higher for navigation lines than for railroads, which in 1906 showed a ratio, for the United States as a whole, of 66¼ per cent. This is not surprising, as out of their own earnings railroads must pay large sums on account of the fixed charges for their roadbed, for which there are no corresponding charges in the case of most navigation companies.

An analysis of the ratio of operating expenses to gross earnings, by districts, is of interest.

	Lumber carriers.	Coal carriers.	Bulk carriers.	Packet lines.	River lines.	All lines.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Great Lakes			69.7	85.7		77.2
Atlantic and Gulf coasts			83.3	79.2		79.8
Mississippi and tributaries		79.3			86.8	83.7
Pacific coast	75.8			*85.7	84.7	85.4

* Ocean packet lines.

The bulk carriers on the Lakes show the smallest ratio of expense. This is natural, as a result of the great predominance of bulk-cargo traffic there and the high degree of specialization thus made possible in carrying and terminal methods. The highest ratio of expenses is for the packet lines on the Mississippi and southern rivers.

The high operating cost of the Pacific coastwise packet lines is somewhat misleading, due partly to the heavy loss of one company in a special branch of business since abandoned. The normal ratio there would be about 81 per cent.

The incomplete nature of the statistics and the absence of information as to the relation between the capitalization of navigation lines and the cost and value of their equipment and property makes impossible a comparison of the net earnings with the actual investment, to show correctly the profitableness of the business. It may be said, however, that in the case of the companies reporting, the average net earnings are a fair rate on the capitalization; but there are wide variations between different companies, some showing a very high rate of return on the capital, others reporting operating expenses in excess of gross earnings.

SHIPPING CONTRACTS AND DOCUMENTS.

Transportation by water is the oldest method of long-distance traffic. It is in large measure governed by a body of world-wide maritime usages of remote origin. These customs have, however, been modified by statute, especially since the development of inland navigation and its closer connection with railroads. Various ports also have local rules.

In securing cargoes, regular steamship lines, like railroads, make use of traffic agents of their own, but in the case of bulk cargoes and "tramp" vessels ship brokers, acting for both parties, are often employed.

CHARTERS AND BILLS OF LADING.

The vessel may be let or hired by a charter, or the vessel may have a regular route, its owner or operator accepting shipments as a common carrier, in which case it is technically known as a "general ship." The two instruments most commonly employed in contracts of carriage are the charter party and the bill of lading. The former is a contract for the whole or a large part of the vessel; the latter for a smaller and varying portion of the vessel's capacity. There are numerous forms of both classes of documents employed, although efforts have been made to secure the use of uniform contracts.

The practice of leasing vessels is quite common throughout the United States. In some instances all the vessels of an operating company are chartered by it from the owners. Some vessels operated in the foreign trade are chartered by the year from foreign owners.

Bills of lading issued by vessels correspond in a general way to those issued by railroads. There is considerable diversity, especially in clauses limiting the liability of the carrier. The New York Produce Exchange steamship bill of lading is one often employed. Some clauses in many bills of lading appear to conflict with the provision in the Harter Act prohibiting a vessel owner from inserting stipulations to relieve himself from the results of negligence.

MANIFESTS.

These correspond to railroad waybills, showing the cargo of vessels on each voyage. In the case of foreign voyages, and on the Great Lakes, manifests must be filed with the customs officers; but they are not ordinarily required to be filed for other coastwise or river routes. This is a serious obstacle to the collection of complete statistics of water-borne traffic in the United States.

GOVERNMENT REGULATION.

The interstate-commerce acts have been applied only in a limited degree to carriers by water; and it is uncertain how far the provisions of these acts as to rates and carriers' liability are intended to apply to water lines. This is in marked contrast with the close supervision over vessels and their officers for the protection of life. In this latter respect water traffic has long been far more closely regulated by government control than railroad traffic. The detailed strictness with which the construction, operation, and maintenance of vessels is watched by the Government, and its complete system of inspection thereof, is in very marked contrast to the almost complete absence of such control over railroads. This difference, also, has borne with some disproportionate weight on the water traffic.

On the other hand, governmental control of rates has been much more complete over railways than over waterways.

MARINE INSURANCE.

Marine insurance charges are an important factor as an addition to the cost of transportation by water, and they must be taken into consideration in comparing the relative economy of rail and water routes.

VARIATIONS IN POLICIES AND RATES.

Since the floating equipment and cargoes protected by insurance are of various kinds, there is a similar diversity in the types and stipulations of insurance policies. As regards vessels, there are river hull policies, ferryboat hull policies, inland hull, tug, yacht, schooner, and steamboat policies. As regards cargoes, there are cotton policies, coal, lake-cargo, and river-cargo policies. There are also blanket policies on hull and cargo and on all the vessels and cargo of particular lines.

There is considerable variety both in the manner of effecting insurance on vessels and cargoes and in rates of premium, not only on the different waterways of the country, but also in respect to the several types of vessels and the freight transported. Inland policies are peculiar in the restrictions upon the routes on which the craft may operate, and in the varying rates of premium on different streams. Some vessels carry only fire insurance, others both fire and marine insurance, and others fire, marine, and port insurance. Often no vessel insurance or insurance of any kind is carried. Some vessel owners are their own insurers, providing special reserve funds for that purpose. Insurance on vessels is usually by the year, often with lay-up clauses applicable to the period during which navigation is suspended.

Cargo insurance in some cases is entirely attended to by the vessel owner on behalf of the shipper or consignee. Generally, however, it is effected on each shipment by the shipper and continues until the vessel reaches the port of destination or for a certain time thereafter. In other cases, however, especially with reference to bulk freight, the vessel owner or owner of cargo lots takes out a blanket policy covering all shipments for a given period.

The great portion of river hulls and shipments seems to be protected by insurance. Differences in the conditions of river improvement, navigability, and river dangers are reflected in the insurance rates. In fact, the cost of insurance is often a determining factor as between rail and river shipments. The rail carrier being practically, by law, the insurer of the freight, insurance on rail freight is a negligible consideration for the shipper. But on water, and especially river traffic, this is by no means so. Instances of river insurance rates are as follows:

A company operating on Virginia and Maryland waterways reports that the insurance premium for a recent fiscal year amounted to 3.1 per cent of the gross receipts. Cargo insurance on the Red River is 0.9 per cent of the value of the goods. On the Mississippi River from Vicksburg to New Orleans cargo insurance is 45 cents per $100, or about 20 cents per bale of cotton, which must be added to the freight rate of 75 cents per bale, thus making the insurance nearly one-third of the freight.

These high and varying rates of insurance not only increase the cost of transportation, but they also indicate the dangers of such traffic and add to the uncertainty and lack of uniformity so detrimental to shippers' interests.

There seems to be a general tendency for marine insurers to work in groups or combinations. A large proportion of the total risks assumed in the United States are taken by foreign companies. In the United States, marine insurance is largely written by corporations instead of by such associations as Lloyds, in England. There are nine important domestic companies, of which only one devotes itself exclusively to marine indemnity, the others combining fire and marine business, their fire-insurance business being larger than the marine.

TAXATION OF VESSELS AND OF NAVIGATION COMPANIES.

CONSTITUTIONAL RESTRICTIONS.

The power over interstate and foreign commerce vested in Congress, together with the specific prohibitions of the Constitution against state tonnage and customs duties without the consent of Congress, restricts the taxing power of the States over navigation as such, while leaving the States free to tax vessels like other property within their respective jurisdictions. Thus a tax on interstate traffic as such is unconstitutional, and the privilege of navigating public waters is not subject to state license tax; but States may under some conditions impose franchise taxes based in substance upon the gross receipts of transportation companies, even though part of them be derived from interstate traffic, or upon the capital stock of companies engaged in interstate commerce.

Tonnage taxes, no matter in what form, may not be imposed by a State on vessels simply because of their use of or presence in a public waterway, although where a State has made improvements in a waterway it may charge a toll for the use of those improvements, in reasonable proportion to the cost and maintenance of such improvements, even if such toll be calculated on tonnage.

Furthermore, a State or municipality may charge wharfage fees for the use of landing places provided by it, even if such fees be fixed on the basis of tonnage.

METHODS OF STATE TAXATION.

One of the common methods employed in the taxation of navigation companies appears to be an assessment of the capital stock at its market value, after deducting therefrom the assessed valuation of the corporation's vessels and other tangible property which are taxed like similar property belonging to individuals. The States using this method are Massachusetts, North Carolina, Alabama, Kentucky, Illinois, Kansas, Minnesota, and North and South Dakota. Several States, however, impose relatively light franchise or license taxes measured by the par value of the stock, and without regard to any taxes assessed upon the tangible property. These States are New Jersey, New York, Delaware, Ohio, West Virginia, Georgia, Texas, Colorado, and California. A number of others tax gross or net receipts as well as the capital stock and tangible property. These States are New York, Pennsylvania, Maryland, Virginia, and South Carolina.

In most of the States water craft of all kinds are assessed and taxed like other personal property, either at the residence of the owners or, what is often the same thing, at the port of enrollment, registry, or license. A few States provide for taxes measured by the gross or net tonnage in lieu of other taxes on such property, on the assumption that the value of vessels is roughly in proportion to size. Vessels engaged in the foreign trade are in several States favored either with exemption from taxation or with very light taxes based upon their net earnings. Massachusetts, which formerly taxed the net earnings or dividends in such cases, now assesses the property, whether belonging to individuals or corporations, at the low rate of one-third of 1 per cent—about one-fifth of the rate of taxation on other property. A low rate of taxation on vessel property is probably of advantage to the State imposing it, because of the ease with which taxation can be evaded in respect of property so easily movable.

FEDERAL TAX.

There is no federal tax on American vessels in domestic trade. The National Government imposes a tonnage tax on vessels entered at ports of the United States from foreign ports, at the rate of 3 cents per ton in the case of vessels from near-by foreign ports and 6 cents per ton when from more distant places, but not to exceed 15 cents per ton per annum in the former case or 30 cents per ton per annum in the latter case.

Part II.—WATER-BORNE TRAFFIC.

Part II deals with the following topics:

(1) The general nature of water-borne traffic, its development, and its present importance.

(2) Through traffic of the Atlantic and Gulf coasts.

(3) Traffic at various North Atlantic ports and on tributary inland waterways.

(4) Traffic at South Atlantic ports and on neighboring rivers.

(5) Traffic on Gulf of Mexico and its tributaries, exclusive of the Mississippi system.

(6) Traffic on the Great Lakes and connecting waterways.

(7) Traffic on the Mississippi River and its tributaries and connecting canals, and the Red River of the North.

(8) Traffic on the Pacific coast and streams tributary to the Pacific.

There are very important differences between coastwise, Great Lakes, river and canal, and harbor traffic, although, owing to the incomplete nature of available statistics, these classes can not always be accurately separated.

Following is a brief statement of the results of this part of the investigation:

Domestic water-borne traffic is mainly in passengers and freight. Both the domestic express and mail movements are unimportant, and except in the coastwise trade and on the Great Lakes the same is true also of the movement of passengers. Of the total of more than 366,000,000 passengers by water reported to the census in 1906, nine-tenths were carried by ferryboats. Those carried by other than ferryboats were less than one-twentieth of the number of passengers carried by rail.

IMPORTANT CLASSES OF FREIGHT.

Freight moved by water includes two general classes—first, so-called package freight, usually, but not always, in bags, boxes, barrels, or other packages, and also referred to as "general merchandise," "miscellaneous merchandise," or "steamboat freight;" and, second, bulk or coarse freight, usually shipped in cargo lots, and embracing the products of mines, fields, and forests. Freight moved by water in American vessels in 1906, including harbor traffic but excluding logs and lumber rafted and floated, aggregated more than 265,000,000 tons, as contrasted with 130,000,000 reported by the census in 1889. Much the larger part of this is domestic traffic, foreign traffic being mainly carried in foreign vessels.

On the coasts and the Great Lakes there was a very marked increase in the traffic from 1889 to 1906, that of the Great Lakes having trebled and that on the Atlantic and Gulf coasts having nearly trebled. On the other hand, on the Mississippi River and tributaries there was an actual decline, and on other inland waters reported separately by the census (mostly canal traffic) there was a very marked decline during this period.

Excluding harbor and raft traffic, the water-borne traffic in American vessels for 1906 amounted to 177,519,758 tons, of which 42.6 per cent moved on the Great Lakes and 36.8 per cent on the Atlantic and Gulf coasts and rivers. Of this traffic, more than one-half the tonnage consists of certain crude minerals (coal, iron ore, stone, and sand). Other bulky mineral products, such as petroleum and other oils, cement, brick, lime, ice, phosphate rock and fertilizer, and pig iron and steel rails constitute the third largest group. Lumber and naval stores form the second largest group, and the movement of logs and timber in rafts, which is not reported, would increase the total for forest products by a large amount. Agricultural products, including grain, flour, fruits and vegetables, cotton, and tobacco, also form an important group in volume and more important if the value of the commodities is considered. The above commodities, most of which are shipped as bulk freight, together form over 80 per cent of the traffic in American vessels.

Package and miscellaneous freight comprises about one-fifth of the movement reported for 1906, and is of the greatest importance on the Atlantic and Gulf coasts, where it represents nearly 30 per cent of the volume of freight handled. The movement of this class of traffic is, however, of varying degrees of importance on all of the water routes of the country.

SPECIALIZATION OF TRAFFIC BY DISTRICTS.

Traffic is considerably specialized by districts. Coal forms the largest tonnage of any single commodity. In 1906 about 70,000,000 tons were shipped, or excluding harbor traffic over 49,000,000, nearly 30 per cent of the total freight in American vessels. The largest part of this movement is that of the North Atlantic coast, but immense quantities of coal are moved on the Great Lakes and also down the Monongahela, Ohio, and Mississippi rivers. Coal is also an item of large relative importance on the canals. On the Pacific coast the movement of coal is of minor importance and is declining with the increased use of petroleum for fuel purposes.

Next to coal comes iron ore, aggregating over 41,000,000 net tons in 1906. Practically the whole of this movement is on the Great Lakes, where it is more than half of the total freight tonnage carried.

Stone and sand, with other building materials, are largely carried on the Atlantic and Gulf coasts and on the rivers of the Mississippi Valley, aggregating about 15,000,000 tons in 1906. These commodities, however, are, for the most part, carried over short distances, in contrast with the long-distance movement of coal and iron ore.

Lumber still represents an important part of the movement by water in all the districts. The census figures for 1906 are over 7,000,000,000 feet, or over 14,000,000 tons, but, lacking the movement by rafts, the statistics of these movements are incomplete. The transportation of grain and flour by water is of largest importance on the Great Lakes, where two-thirds of the 7,669,000 tons of these commodities reported for 1906 were carried. The domestic trade in grain on the Lakes shows some decline in recent years. Crude petroleum is moved by tank steamers in large quantities on the Atlantic, Gulf, and Pacific coasts.

The movement of phosphate and fertilizer, cotton, fruits, vegetables, tobacco, and naval stores, is mainly on the Atlantic and Gulf coasts. Ice moves chiefly from ports on the larger rivers of Maine and from the Hudson River to New York City and southern ports. This traffic has declined, probably due to the development of ice manufactories. Considerable crude phosphate rock is shipped from Florida and South Carolina, while other fertilizer materials and fertilizers are shipped from North Atlantic ports to the South. Naval stores and cotton are shipped mainly from the South Atlantic and Gulf to northern ports. Pig iron and steel rails are items of some importance on the Atlantic and Gulf coasts and on the Great Lakes.

THROUGH MOVEMENT ON THE ATLANTIC AND GULF COASTS.

The total traffic in American vessels on the Atlantic and Gulf coasts, as reported by the Bureau of the Census for 1906, amounted to 140,512,043 tons, including harbor traffic, and to 65,360,958 tons, excluding harbor movement. Most of this is domestic traffic. The Atlantic and Gulf coasts may be divided into three districts—North Atlantic, South Atlantic, and Gulf. There is a very large through movement between these districts, and also a large local traffic within the North Atlantic district and some local traffic in the other two districts.

Four Atlantic ports, sometimes called "the Atlantic portals"—Boston, New York, Philadelphia, and Baltimore—stand out conspicuously in coastwise as also in foreign commerce. Each of these is the distributing point for an important area and also the terminal of trunk lines of railroads connecting the agricultural and manufacturing sections with the seaboard. Among other ports of importance on the Atlantic and Gulf coasts are Portland, Providence, Wilmington, Del., Norfolk, Wilmington, N. C., Charleston, Savannah, Jacksonville, Mobile, New Orleans, and Galveston.

At the various ports traffic is specialized to a large extent. Some ports are identified with the movement of certain commodities, while at the larger ports special terminals are provided for different classes of traffic.

Coal is shipped from about a score of terminals at the five ports of New York, Philadelphia, Baltimore, Newport News, and Norfolk. Nearly 39,000,000 tons were shipped from these five ports in 1906, and 44,000,000 in 1907, over 60 per cent from terminals in and about the port of New York. Much of this moves only in the harbors and for short distances locally; but nearly half is delivered by barges at numerous points along the New England coast, over 1,000,000 tons going annually to New Haven, over 2,000,000 tons to Providence, and about 4,500,000 tons to Boston.

Lumber and naval stores are shipped from Jacksonville and Fernandina, Fla., Brunswick and Savannah, Ga., Charleston and Georgetown, S. C., Wilmington, N. C., and Norfolk and Newport News, Va., on the South Atlantic, mostly to points in the Middle Atlantic States. Receipts of southern pine at New York by water are over 450,000,000 feet. There is also a movement of eastern spruce from New England ports. Lumber is still carried to a large extent in sailing vessels, but steamships and steam-towed schooner barges are doing an increasing proportion of the business.

Cotton still occupies an important position in the Atlantic and Gulf coastwise trade. Recently there have been important changes in the relative rank of the different ports, and a general substitution of steam for sailing vessels in the carriage of this commodity. Galveston is the most important shipping point for cotton, both foreign and coastwise, but is closely followed in the coastwise trade by Savannah and Norfolk. New York is the principal receiving port, and Boston ranks second.

Crude and refined petroleum is shipped in large quantities from Port Arthur and Sabine Pass, Tex., amounting to over 10,700,000 barrels in 1906 and 8,700,000 barrels in 1907. There is also a large movement of refined oil from refineries adjoining New York and Philadelphia to New England and southern ports. Crude phosphate is shipped mostly from points in Florida and South Carolina; and fertilizers and fertilizer material are received in large quantities at southern ports from the North.

Another important movement is the interchange of general merchandise between the ports of New York, Philadelphia, and Baltimore and New England ports, and between the principal North Atlantic and the South Atlantic and Gulf ports. Other through movements include ice, fish, and granite from New England.

Trade with Porto Rico is carried on mainly from New York and New Orleans. Shipments to the United States consist mostly of sugar, with considerable tobacco and cigars and fruits. Shipments to Porto Rico include a large variety of manufactured goods.

NORTH ATLANTIC PORTS, RIVERS, AND CANALS.

Turning to the traffic within the three principal districts, above distinguished, it appears that much the greater part of this is in the North Atlantic district. This may be further divided into several subdistricts.

THE "GULF OF MAINE"—PORTLAND AND BOSTON.

This is the great indentation between Nova Scotia and Cape Cod. It is further indented by numerous bays and harbors and tidal rivers, the most important of which are Lubec Channel, Penobscot Bay, Kennebec River, Casco Bay, Portsmouth Harbor, Massachussetts Bay (including Boston Bay), and Cape Cod Bay. There is a considerable local movement in coastwise vessels between and along these bays and rivers. Boston and Portland are its most important ports. Portland has a considerable foreign commerce in grain and flour as well as a large coastwise trade carried chiefly by sailing vessels. Its total freight tonnage (domestic and foreign) in 1906 was 2,547,000, about one-half of which was coal. Boston, the chief port of New England, is one of the most important in the country, ranking second in foreign trade to New York, and third of the Atlantic ports in domestic trade. Coal is the largest item of coastwise receipts at Boston, amounting to 4,500,000 tons annually. Lumber receipts in 1906 amounted to 165,000,000 feet, more than two-thirds from the South. Much cotton is also received, and there is an important movement of general merchandise between Boston and other Atlantic ports north and south. The total traffic in American vessels at Boston, as reported by the census for 1906, was 7,420,574 tons, mainly coastwise.

SOUTH COAST OF NEW ENGLAND.

This coast has a series of sounds and bays furnishing protected or "inside" routes from New York to various ports in Connecticut, Rhode Island, and southeastern Massachusetts, where connection is made by rail with many industrial communities. The projected Cape Cod Canal will extend the inside route practically to Boston. The "outside" route south of Long Island is used in the trade from the Middle and South Atlantic ports.

New Bedford, on Buzzards Bay, has a large trade in coal, cotton, and whale oil. Narragansett Bay has several ports of some importance; Newport has a considerable trade in coal, lumber, and fish, and is also used as a harbor of refuge for vessels and barges. The city of Fall River, at the entrance to Taunton River, has an important coasting trade, large cargoes of coal and cotton being brought to its factories and also large quantities of steamboat freight (or general merchandise) for transshipment by rail to Boston and other points. Providence is of considerable importance in the coastwise trade, with regular lines of steamers to New York and Baltimore. Coal is the most important article received, but there is also a large volume of general merchandise and a movement of lumber, building materials, oil, and oysters. The total water-borne commerce for 1906 was over 3,000,000 tons, mostly domestic.

The commerce of Long Island Sound includes most of that to and from points in Narragansett Bay and a large part of the traffic from New York to the eastern coast of New England, besides receipts and shipments at the rivers and harbors along the Sound. The Thames River is a tidal stream for a distance of 15 miles from its mouth to Norwich. New London, on this river, has a large trade in general merchandise and coal. On the Connecticut River there is considerable commerce, both in steamers and barges, as far as Hartford, Conn., consisting mainly of coal, lumber, building materials, and miscellaneous steamboat freight. New Haven is commercially the most important harbor on Long Island Sound, with a large trade in coal and general merchandise, and a considerable movement of lumber, oysters and shells, steel billets, and petroleum products. The water-borne commerce in 1906 amounted to 2,300,000 tons, nearly all domestic. Bridgeport, a manufacturing city, has a large carrying trade by water. Less important points include Norwalk, Stamford, and Port Chester.

PORT OF NEW YORK.

The port of New York covers an extensive area, embracing both Upper and Lower New York bays, and their connecting channels, with a total water front of about 450 miles, of which about 125 miles are available for ocean steamships. New York is by far the most important center of water-borne commerce in the United States. Its foreign commerce is many times that of any other port, and nearly one-half the total foreign commerce of the country; and the coastwise and local harbor traffic is also many times that of any other port in the United States.

According to the census report for 1906, the total traffic of New York Harbor and adjacent points is as shown below:

	Shipments.	Receipts.	Total.
Traffic in American vessels (mostly coastwise):[a]	*Tons.*	*Tons.*	*Tons.*
New York City	8,598,374	17,507,906	26,106,280
Adjacent ports[b]	6,758,978	960,350	7,719,328
Total	15,357,352	18,468,256	33,825,608
Foreign trade (estimated)	14,963,162	10,049,167	25,012,329
Harbor traffic			55,131,418
Grand total	30,320,514	28,517,423	113,969,355

[a] So far as foreign trade is carried in American vessels, there is a duplication in the total, but much the greater part of the trade in American vessels is domestic trade.

[b] Hoboken, Jersey City, Newark, Perth Amboy, and South Amboy.

NEW YORK STATE INLAND WATERWAYS.

The inland water routes of the State of New York embrace the New York State canals and the Hudson River, which connect the Lakes with the port of New York by three routes, and Lake Champlain, which serves also Burlington, Vt. The commerce of the Hudson consists principally of lumber, grain, ice, building materials, including brick, and coal. There is also an extensive passenger traffic. There has been a considerable falling off in river freight at Albany from 5,071,000 tons in 1899 to 3,326,000 tons in 1906.

Up to 1855 the traffic on the New York canals was more than twice that of the railroads crossing New York State; until 1864 it was greater than that of the railroads, and in 1872 the canal traffic was one-third of the total traffic crossing the State. Since that time, and in spite of the abolition of canal tolls, there has been a steady decline until the past ten years. During the latter period canal traffic held its own in absolute amount, but the decline in the proportion of the total amount of traffic carried by the canals has been continuous, until at present the New York canals carry only 3 per cent of the total traffic across New York State. The total traffic on these canals in 1907 was 3,408,000 tons. Furthermore, in the last few years there has been an increase in local and way canal freight and a decline in through traffic, so that the way traffic now constitutes more than two-thirds of the total canal tonnage. Stone, lime, and coal together form the largest proportion of the total tons moved; grain, lumber, and wood have declined, but are still among the important articles.

The commerce of Lake Champlain consists principally of coal, pulp wood, building materials, and general merchandise.

DELAWARE BAY AND PHILADELPHIA.

The commerce of Delaware Bay and its tributaries and connecting canals is exceeded by only two or three local districts in the United States. It includes the extensive trade of Philadelphia, the important traffic of Wilmington, Del., and a considerable local movement on the Delaware River, its tributary streams, and a number of private canals.

The port of Philadelphia is on the Delaware River, about 86 miles above the Capes of the Delaware. Greenwich and Port Richmond, important shipping points for the coastwise movement of coal, are within the port of Philadelphia. Marcus Hook, with a great petroleum traffic, is near by. Philadelphia is well situated with reference to waterways, and connected with many inland points, as well as domestic and foreign ports. It is one of the great exporting points and also an extensive domestic commerce. Domestic shipments on the Delaware River for 1906, as reported to the United States engineers, amounted to 12,228,000 tons, and domestic receipts by water to 8,349,000 tons, a total of 20,577,000 tons. This total involves some duplication in the case of local movements. The census report gives the traffic in American vessels at Philadelphia for 1906 at 7,934,941 tons, excluding harbor traffic.

Wilmington, Del., has some foreign trade and a considerable domestic commerce by water, while the important shipbuilding and other manufacturing interests of the city are largely dependent upon the navigation facilities.

Connecting with the Delaware River are a number of tributaries and private canals—Cooper and Mantua creeks, Mispilion and Smyrna rivers, the Morris, Delaware and Raritan, Lehigh, and Delaware Division canals, the Schuylkill Navigation, and the Chesapeake and Delaware Canal connecting Delaware River and Chesapeake Bay. The traffic movement on these minor waterways is comparatively small, and that on the canals, except on the Chesapeake and Delaware Canal, has been slowly declining during the past ten years.

CHESAPEAKE BAY.

This is the largest indentation on the Atlantic coast. It is the center of a large foreign and coastwise movement converging at Baltimore, Newport News, and Norfolk, and there is also a large local movement on the bay and its numerous tributary rivers. The rivers of the eastern shore are of less general importance than those of the western, but are much used by local steamboats and small craft engaged in oyster dredging and local trade.

Baltimore is located on the north branch of the Patapsco River about 11 miles from its entrance into Chesapeake Bay. At this port are the terminals of a number of steamship lines operating to many points on the Atlantic coast and on Chesapeake Bay and its tributary streams. In the foreign trade Baltimore ranks fourth among the Atlantic ports in the tonnage of vessels. In the coastwise trade the largest volume consists of coal shipped north and south, amounting to 3,400,000 tons in 1906 and 4,070,000 tons in 1907. There is also an important movement of package freight. The total traffic in American vessels, according to the census, was 5,437,850 tons in 1906, nearly all coastwise.

Washington is the center of a considerable trade in coal, lumber, and ice, and a market for farm produce, oysters, and fish moved over the Potomac and Anacostia rivers. Traffic on the Chesapeake and Ohio Canal consist almost entirely of bituminous coal from Cumberland, Md., to Washington. There is also some traffic on the Rappahannock and York rivers.

SOUTH ATLANTIC PORTS AND RIVERS.

The water traffic within the South Atlantic divison is small as compared with that of the North Atlantic division. The greater part of the domestic traffic of South Atlantic ports is with the North. There is little or no local movement between these ports on the open sea, but the numerous rivers, bays, sounds, and lagoons along the South Atlantic seaboard have a considerable local traffic in the staple commodities of this section, with return shipments of plantation supplies and general merchandise. The inland manufacturing towns are generally supplied with coal by rail from local southern coal fields, and there is accordingly no large water movement of coal to southern ports for inland distribution. The foreign trade is carried very largely in tramp steamships, but the coastwise trade is sufficiently regular and large to employ regular lines of steamers to northern ports.

Norfolk and Newport News, at the southern end of Chesapeake Bay, near Hampton Roads, have a large and varied commerce, including important shipments of coal. The total water-borne commerce of Norfolk reported to the United States engineers for 1905 was 10,914,000 tons, and for 1906, 15,662,000 tons. The traffic in American vessels at Norfolk and Newport News, according to the census of 1906, was 10,488,576 tons, practically all coastwise.

Wilmington, the chief port of North Carolina, is on the Cape Fear River, about 27 miles above its mouth. Its total commerce by water for 1906 was about 800,000 tons, including logs and lumber rafted; traffic in American vessels was 267,139 tons.

The two principal ports of South Carolina are Georgetown, on Winyah Bay, and Charleston, at the confluence of Cooper and Ashley rivers. The commerce of Georgetown for 1906 amounted to 393,000 tons. Charleston has some foreign and considerable coastwise trade, but has declined as a cotton port. The foreign and coastwise commerce for 1906 amounted to 835,000 tons; traffic in American vessels, 718,680 tons.

Savannah, on the Savannah River, about 15 miles above the entrance, is the principal port of Georgia, and is one of the most important South Atlantic seaports for the shipment of cotton, lumber, and naval stores, which are received from the interior by rail and to some extent by river. The traffic in American vessels in 1906 was 1,490,363 tons. Brunswick, Ga., is also an important shipping point for lumber.

On the Atlantic coast of Florida are the two important ports of Fernandina and Jacksonville, with a total commerce by water in 1906, as reported to the United States engineers, of 955,000 and 2,115,000 tons, respectively. The census gives the traffic in American vessels at Jacksonville at 993,566 tons. At the southern end of the peninsula there is a small movement centering at Miami.

RIVERS AND OTHER INLAND ROUTES.

There is considerable traffic on the James River. Through the Dismal Swamp and Albemarle and Chesapeake canals there is some movement of forest products and other traffic between Norfolk and the rivers and sounds of North Carolina. There is also considerable local traffic on the tributaries of Albemarle and Pamlico sounds and some on the Cape Fear River. In South Carolina there is a local movement of some importance on the Waccamaw, Pedee, and Santee rivers. There is also some local traffic, mostly of lumber, on the Savannah, Altamaha, and Ocmulgee rivers in Georgia, and a considerable movement on the St. Johns River in Florida. The inside coast routes have but little traffic.

GULF PORTS AND RIVERS, EXCLUSIVE OF THE MISSISSIPPI.

PRINCIPAL GULF PORTS.

The chief Gulf ports, in the order of importance, are New Orleans, Galveston, Mobile, Port Arthur, Pensacola, Tampa, and Key West. Each has considerable export and coastwise trade moved by steamship lines and sailing vessels. Of coastwise shipments, the greater part are to northern ports, the remainder representing a local movement between Gulf ports.

Several steamship lines run from Mobile to ports in Central America, Mexico, and Cuba, and a number of tramp steamers to Europe. A steamship line operates between Mobile and New York, and several local lines run to neighboring Gulf ports and river ports, including Montgomery. Important bulk commodities handled at Mobile are lumber and timber, cotton, and coal. The total commerce reported by the United States engineers for 1906 was 1,373,000 tons, of which 302,000 tons were coastwise. Traffic in American vessels was 363,000 tons, according to the census report.

New Orleans is on the Mississippi River about 100 miles from the Gulf. The port facilities for handling cargoes are excellent. Rail lines from all directions converge here, and there are regular lines of steamers to Tampa, Baltimore, and New York, and also to Mexico, Central America, Panama, Habana, Porto Rico, and European ports, besides many tramp vessels. In the foreign trade, New Orleans is an important point of import for the products of Central and South America and the West Indies. In exports it is also of much importance, particularly in the cotton trade. New Orleans is a natural port of export for cotton and grain. In the coastwise trade shipments are made up of cotton, rice, citrus fruits, and other agricultural products, lumber, sugar, molasses, etc., the most important traffic being with New York. The total water-borne commerce of New Orleans (foreign, coastwise, and river) for 1906 was 5,702,000 tons, three-fifths of which was foreign trade. The coastwise movement reported to the United States engineers amounted to 694,000 tons. According to the census, the foreign and coastwise traffic in American vessels at New Orleans for 1906 was 1,924,484 tons. The river commerce of New Orleans will be considered in connection with the Mississippi River.

Galveston is the principal port of Texas, and the second Gulf port in importance. According to the United States engineers, it has the largest coastwise trade of any of the Gulf ports, amounting in 1906 to 832,000 tons. The census reports the traffic in American vessels for 1906 at 1,695,897 tons. Several important lines of steamers run regularly to Atlantic ports, and it also has a large foreign trade in cotton, cotton-seed products, sugar, coal, and general merchandise.

TRIBUTARY RIVERS.

The maritime commerce of the Gulf ports is fed to some extent by tributary rivers. Of these, the most important are the rivers of the Alabama system, including the Mobile, Alabama, Coosa, and Tombigbee. Other Gulf tributaries with local traffic of some importance include the Withlacoochee, in Florida; the Apalachicola and its tributaries, in Florida and Georgia; the Pascagoula, Leaf, and Chickasahay, in Mississippi; the Chefuncte and Calcasieu rivers and bayous Plaquemine and Teche, in Louisiana, and the Neches, Sabine, and San Jacinto rivers, in Texas.

THE GREAT LAKES AND CONNECTING WATERWAYS.

The principal characteristics of Lake commerce are the preponderance of eastbound over westbound shipments and the fact that the traffic is mainly in a few commodities—iron ore, grain, coal, and lumber. There is a considerable movement of miscellaneous and package freight, both local and through, but it is small compared with the enormous bulk-freight traffic in the crude products of contiguous mines, forests, and grain fields.

Through traffic constitutes the greater part of the total freight movement. The main course of this lies between the western extremity of Lake Superior and the southern shore of Lake Erie.

The Lake traffic was not reported as a whole prior to 1889, when, according to the Census, the domestic traffic amounted to 25,266,974 net tons. The domestic traffic amounted to 45,000,000 tons in 1901, and in 1907 to more than 80,000,000 (shipments 83,507,000 and receipts 81,124,000 net tons).

MOVEMENT OF COMMODITIES.

Iron ore and coal form by far the greater part of the Lake traffic, and furnish together 98 per cent of the total increase from 1905 to 1907. The movement of lumber during these years has declined in importance; other traffic, outside of ore and coal, has remained about stationary.

Since 1890, with the development of the Lake Superior mines, the United States has taken first rank among the world's iron producers. Of the total domestic production of iron ore, approximately 80 per cent was transported by way of the Great Lakes (41,000,000 net tons in 1906 and 45,500,000 net tons in 1907), constituting in some years more than half of the total domestic Lake traffic.

Next in volume to iron ore, and first in the westbound Lake traffic, is the westbound movement of coal. This was over 21,000,000 tons in 1907, representing about a fourth of the domestic Lake traffic.

In the movement of flour and grain (eastbound) there is active competition between the Lake and all-rail routes, and with the decline in export trade the domestic movement on the Lakes has remained practically stationary in recent years, at about 150,000,000 bushels of grain and 1,300,000 tons of flour. There has been an increase of traffic from American ports to Canada and also between Canadian ports.

The traffic in logs and lumber is decreasing in volume and still more in relative importance. Nevertheless, it still constitutes one of the leading items.

Some of the less important forms of traffic are the movement of copper, salt, pig iron, and package and miscellaneous freight. About 100,000 tons of copper ore are annually shipped, mainly from the copper district in the Upper Peninsula of Michigan. Salt is shipped by Lake in considerable quantities from Manistee and Ludington, Mich., and in smaller quantities from Buffalo and other points. Pig iron moves in small lots between a considerable number of ports. Package and miscellaneous freight forms about a tenth of the total traffic.

TRAFFIC BY LAKES AND PORTS.

Lake Superior shows the largest volume of shipments of any of the Great Lakes, domestic shipments aggregating over 40,000,000 tons in 1906. About 65 per cent of the total traffic of the Lakes passes in or out of Lake Superior through St. Marys Falls canals. Lake Erie has the largest receipts (43,600,000 tons in 1906 and 47,000,000 in 1907 in the domestic traffic), is second in volume of shipments (18,450,000 tons in 1906), and has the largest proportion of the total traffic. Lake Michigan ranks third, but has the largest amount of local traffic.

Notwithstanding the large number of Lake ports, about a dozen ship and receive 80 per cent of the water-borne traffic. Duluth-Superior is the most important port for shipments and has the largest water-borne traffic of any of the Lake ports, aggregating over 29,000,000 tons in 1906, mainly ore, grain, and coal. Chicago and Milwaukee are among the leading ports, both for shipments and receipts. The Lake commerce of Chicago amounts to about 10,000,000 tons annually, and that of Milwaukee to 6,000,000 tons. Buffalo and Cleveland are also ports of first importance, both in the volume and in the variety of their commerce, and Buffalo has the largest receipts of any of the Lake ports. The Lake commerce of Buffalo for 1906 exceeded 15,500,000 tons (domestic traffic 14,345,000 tons), and, including canal traffic, the total water-borne commerce of Buffalo was over 17,320,000 tons. The Lake commerce of Cleveland for 1906 was 12,247,000 tons (domestic traffic 11,670,000 tons). Other important but more specialized ports include Two Harbors, Ashland, and Marquette, on Lake Superior, and Escanaba, on Lake Michigan, for shipments of ore; Toledo, Ashtabula, Lorain, Conneaut, and Erie, on Lake Erie, for receipts of ore and shipments of coal, and Tonawanda for receipts of lumber.

MISSISSIPPI RIVER AND TRIBUTARIES.

This is the greatest of our inland-river systems, and belongs in a class by itself. It includes not only the Mississippi itself, but also the Ohio, Missouri, Illinois, Arkansas, Ouachita, Red, and Yazoo rivers, with their tributaries, together with a number of other rivers of minor importance. The state canals of Ohio and Illinois are also connected with this system.

The commerce of these various waterways has not kept pace with the general industrial progress of the Middle West. The methods of competition of railroads and the limitations imposed in the competition of boat lines with railroads by the physical characteristics of the rivers in their present condition are the prime causes that have contributed to the decline of river traffic. The boat lines have been handicapped in their competition with rail carriers by the tortuousness of the channel and by the limited and varying depths, causing at times a practical suspension of traffic. They have made little advance in methods for a long time, while the railroads have made important improvements both in physical conditions and in business methods. These improvements, adapted to the changing needs of commerce, in the absence of corresponding improvements in the rivers, have resulted disastrously to boat lines. To-day the principal long-distance shipments by river consist of coal from the Ohio and its upper tributaries to lower Ohio and Mississippi River points, and of logs, lumber, and railroad ties on the whole system, the bulk of the traffic moving downstream.

OHIO RIVER AND TRIBUTARIES—PITTSBURG.

The Ohio with its tributaries has now the most important river traffic in the country. Coal carried in barges from the Monongahela and other tributaries forms the largest part of this movement. Lumber, sand, and gravel are other bulk commodities moved in barges. Logs and timber are rafted in considerable quantities. There is also a considerable amount of miscellaneous and manufactured articles transported in mixed cargoes on packet steamers. In the latter movement local traffic is relatively more important than formerly, owing to the disappearance of through packet lines.

Pittsburg has now the largest river commerce of any inland city in the country. Coal from the Monongahela is received in large quantities, and there is a large harbor movement of sand. Receipts and shipments by river for 1906, according to the Census, amounted to 6,854,575 tons, and including harbor traffic to 8,956,697 tons. Reports to the United States engineers show a total traffic in Pittsburg Harbor for 1906 of 12,927,975 tons.[a] At Cincinnati receipts and shipments by river for 1906 amounted to 2,363,215 tons; at Louisville to 1,203,727 tons, the total river traffic at Louisville being reported to the United States engineers at 1,436,674 tons. Other places of importance are the Ohio and its tributaries include Wheeling, Parkersburg, Marietta, and Evansville; Nashville, on the Cumberland River; Knoxville, Chattanooga, and Florence, on the Tennessee River, and Cairo, at the junction of the Ohio and Mississippi. Traffic on the Ohio state canals is unimportant.

---

[a] This probably includes the movement of coal from the Monongahela River to points on the Ohio below Pittsburg, which simply passes through Pittsburg Harbor.

The traffic of the Ohio River and its more important tributaries for 1906 is shown in the following table:

Rivers.	U. S. Census.[a]		U. S. engineers,[b] total traffic.
	Shipments.	Receipts.	
Monongahela	8,925,923	545,716	11,817,128
Muskingum	13,826	11,073	28,433
Little Kanawha	11,239	6,953	70,289
Kanawha	975,031	63,832	1,227,703
Big Sandy	1,776	4,887	205,452
Kentucky	....	....	184,244
Green and Barren	305,144	80,902	416,906
Wabash	42,427	30,537	....
Cumberland	348,697	178,951	558,250
Tennessee	678,501	472,759	1,578,700
Ohio	3,142,097	12,296,037	11,427,784
Other[c]	782,144	345,299	....
Total	15,226,805	14,036,946	....

[a] Excluding logs and rafted lumber.
[b] Including logs and lumber.
[c] Allegheny and Kentucky rivers.

The statistics of the United States engineers give the total traffic on each river, and a total of these figures would duplicate the traffic moving from one stream to another. Shipments and receipts on the whole Ohio system represent practically the same traffic. The total shipments should indicate the total traffic of the Ohio system, but the census figures do not include the movement of rafted logs and lumber, and including this and harbor traffic (2,354,000 tons), the total shipments on the Ohio and tributaries were probably about 20,000,000 tons.

The census figures show a considerable decline on practically all of these rivers except the Monongahela from 1889 to 1906, and a small decline on the Ohio system as a whole; but the principal decrease indicated is in lumber, the rafted movement of which was partly reported in 1889 and not in 1906. Including coal, the total traffic has probably increased, but shipments of miscellaneous merchandise decreased from 2,819,000 tons in 1889 to 1,314,000 tons in 1906.

UPPER MISSISSIPPI,—ST. LOUIS.

The commerce of the upper Mississippi and its tributaries is relatively unimportant and declining. It consists mainly of local traffic, largely of rafted logs and lumber, and of sand. Traffic on the canals connecting the Mississippi with the Great Lakes is even less important. St. Louis is a converging point for traffic from the upper Mississippi and to a slight extent from the lower Mississippi, the Missouri, the Illinois, the Ohio, the Cumberland, and the Tennessee rivers.

But river commerce at St. Louis has declined steadily during the past fifteen years. The St. Louis Merchants' Exchange reports shipments and receipts of 1,266,000 tons in 1890, of 757,000 tons in 1900, and only 417,000 tons in 1906. The census reports the total shipments and receipts in 1906 as 743,981 tons, including 309,000 tons of sand and stone. The harbor traffic is reported at 969,000 tons.

LOWER MISSISSIPPI,—MEMPHIS AND NEW ORLEANS.

This includes the river from St. Louis to New Orleans. Here the most important through traffic is coal from the Ohio. At Memphis, Greenville, Vicksburg, Natchez, and other places there is some river traffic in coal, lumber, and plantation products and supplies. Memphis is one of the few ports on the Mississippi showing an increase in river traffic in recent years. The traffic in 1906 was 857,000 tons, and that at Vicksburg 375,000 tons. At New Orleans the receipts of bituminous coal by river from the Ohio are estimated at about 1,200,000 tons annually. Cotton, cotton seed and its products, sugar, molasses, and rice are also received at New Orleans from various points on the lower Mississippi and other streams in this territory. There is also considerable traffic in crude petroleum from Louisiana, on the lower Mississippi. The various short canals more or less directly connected with the New Orleans river trade are commercially of comparative unimportance. The total river traffic at New Orleans in 1906, according to the census, was 1,144,113 tons, and according to reports to the United States engineers was 1,666,000 tons.

Below is given a summary of the traffic reported on the several sections of the Mississippi and some of its tributaries (other than the Ohio) for 1906:

Rivers.	U. S. Census.[a]		U. S. engineers, total.[b]
	Shipments.	Receipts.	
	Net tons.	*Net tons.*	*Tons.*
Upper Mississippi	595,885	597,025	5,282,319
Illinois	105,826	106,002	
Missouri and other tributaries	1,056,390	1,051,474	573,348
Total	1,758,101	1,753,501	5,855,667
Lower Mississippi	[c]2,329,350	3,487,137	
St. Louis to Cairo			458,016
Cairo to Memphis			1,719,893
Memphis to Vicksburg			2,355,901
Vicksburg to New Orleans			2,554,396
St. Francis	(d)	(e)	151,015
White	43,933	25,433	127,812
Arkansas	24,994	35,671	104,593
Yazoo	108,357	62,325	227,611
Ouachita and Black of Louisiana	25,136	16,998	171,952
Red	14,417	8,481	112,273
Other rivers		[e]102,401	
Total	2,546,187	3,740,646	

[a] Excluding logs and rafted lumber.

[b] Including logs and lumber.

[c] Including the Atchafalaya, Black of Arkansas, Black Bayou, Lafourche, Macon Bayou, St. Francis, and Tensas.

[d] Included in lower Mississippi.

[e] Included in other rivers.

The traffic reports to the United States engineers give each stream and the sections of the lower Mississippi separately, and a total of these would include duplications to a large extent. The Census figures, on the other hand, do not show the movement of logs and rafted lumber, while the shipments on the lower Mississippi do not include the coal movement from the Ohio. The shipments on the upper Mississippi and the receipts on the lower Mississippi indicate a total traffic on the Mississippi of 5,500,000 tons, excluding logs and rafted lumber and harbor traffic. Including rafts and harbor traffic, the total movement on the Mississippi and tributaries, exclusive of the Ohio system, is probably about 12,000,000 tons.

For the entire Mississippi system, the total shipments and receipts from one port to another, according to the Census as shown below, amounted to 19,531,093 tons in 1906. Including rafts, the movement would be about 25,000,000 tons, and including also harbor traffic (5,190,291 tons) the total would be about 30,000,000 tons.

	Shipments.[a]	Receipts.[a]	Harbor movement.
	Net tons.	*Net tons.*	*Tons.*
Ohio River system	15,226,805	14,036,946	2,354,147
Upper Mississippi system	1,758,101	1,753,501	482,099
Lower Mississippi system	2,546,187	3,740,646	2,354,054
Total	19,531,093	19,531,093	5,190,291
Carferries (estimated)			6,905,597

[a] Excluding rafts.

The Census reports show a large decrease in traffic on both upper and lower Mississippi and for the whole Mississippi system from 1889 to 1906. The extent of this decrease is, however, somewhat exaggerated by the omission of rafted logs and lumber from the statistics of 1906, although these were partially included in 1889, and the largest decrease indicated is in the movement of lumber. But the movement of grain, cotton, and miscellaneous merchandise has fallen to small proportions; and while coal, petroleum, and sand have increased, the total traffic on the whole system is undoubtedly a good deal less than in 1889. The most important increase has been the coal traffic of the Monongahela; there has been an increase of miscellaneous freight on the Cumberland, the Tennessee, and the Yazoo rivers, and the total volume of traffic on the Yazoo has increased to some extent.

PACIFIC COAST AND TRIBUTARIES.

The traffic of the Pacific Coast States is still mainly in raw materials and agricultural products, such as wheat and its products, barley, live stock, fruits, hops, and the products of forests and streams. A recently developed traffic has followed the discovery of oil fields in southern California. Generally speaking, the articles mentioned, with the wool, live stock, and minerals of the Rocky Mountain States, constitute most of the traffic in this territory, either coastwise, by river, or by rail.

The important political events of the past few decades have increased considerably the water-borne commerce of the Pacific coast. The mining and commercial development of Alaska, as well as the demand on the part of oriental countries for the products of the West, have aided in this development, as have also the extension of railroad facilities and the introduction of new crops and industries. One serious drawback has been the scarcity of coal, which is now being partially met by the use of oil for fuel purposes.

The principal bulk coastwise shipments are products of the forests and petroleum. Lumber is moved in large and increasing quantities from Puget Sound, the Columbia River, and the coasts of Washington, Oregon, and upper California. Cargo shipments from Washington and Oregon have increased from 398,000,000 feet in 1894 to 1,443,000,000 feet in 1907; and, including upper California, the total cargo shipments for 1907 were 1,880,000,000 feet. Most of this movement is coastwise.

Petroleum is shipped, mainly in tank steamers, from Port Harford and other points between San Diego and San Francisco to coast points and Hawaii. Shipments in 1906 amounted to nearly 11,000,000 barrels, or about 1,700,000 tons. Some grain moves coastwise from Oregon and Washington to San Francisco, receipts at the latter point amounting to 3,848,000 bushels in 1906 and about the same in 1907. There is a considerable movement of coal by water from Puget Sound and Coos Bay (Oregon) to other Pacific coast points, largely to San Francisco, in vessels employed also in carrying lumber and general merchandise, but there is no regular and exclusively coal carrying fleet. Shipments of coal from Seattle and Tacoma amounted to 605,000 tons in 1906 and 701,000 tons in 1907. Receipts of coal at San Francisco (including imports from British Columbia and Australia) amounted to about 800,000 tons in each of these years.

Traffic between the Pacific Coast States and Alaska and, of course, Hawaii, is carried by water. Most of the trade to Alaska is from Puget Sound ports, steamship companies operating principally from Seattle. The largest share of the Hawaiian trade is from San Francisco, but there is also a considerable amount from Puget Sound and some vessels from the Atlantic coast.

There is a considerable trade between San Francisco and Puget Sound and the Philippine Islands carried by way of Hongkong, as there is no direct line from the Pacific coast to Manila; but the larger part of the trade with the Philippines is from New York, and a notable part of the return movement comes to Boston.

The four leading ports on the Pacific are San Francisco, Portland, Seattle, and Tacoma. Each is the center of numerous water routes and the terminus of transcontinental lines of railroad. From San Francisco the shipments in American vessels in 1906 amounted to 1,656,614 tons, from Seattle 856,988 tons, from Portland 492,573 tons (total domestic traffic by water 648,497 tons), and from Tacoma 270,256 tons. On the Pacific coast generally a larger proportion of the trade in American vessels is foreign trade than on the Atlantic coast. Grays Harbor and Humboldt Bay are important lumber shipping points; Port Harford, in San Luis Obispo Bay, is an oil port; the ports of Los Angeles receive large quantities of lumber and general merchandise, and San Diego has a considerable trade by water.

There is some local traffic on several groups or systems of rivers on the Pacific coast. On the tributaries of Puget Sound there is a large local movement of logs, aggregating 1,200,000,000 feet in 1906; and a small amount of local traffic of other kinds. On the Columbia River there is some traffic on the upper river and tributaries, and a larger river commerce below Portland, including an extensive movement of logs. On the short rivers and bays along the coast of Washington, Oregon, and upper California, there are large numbers of logs moved and a small amount of general traffic. The most varied river traffic is on the rivers of central California, where there is a considerable movement of grain, flour, and general merchandise, centering at Sacramento and Stockton.

Part III.—PORT TERMINALS.

The control of port terminal facilities forms the key to the important question of effective competition with railroads on the part of water lines; but to a very great extent the water fronts of important ports, or the most available parts thereof, are so controlled by railroads and their allied water lines as practically to eliminate effective competition. In many cases the railroads have acquired water-front property by purchase or condemnation because it was the most available location for their tracks and terminals, or because they possessed greater foresight than other investors as to the potential value of such property; in other cases, however, railroads have gained possession of valuable water fronts by encroachments, which have sometimes ripened into legal titles through the neglect of municipalities or other riparian owners.

Railroad control of city water fronts is very extensive. An important case of such control is the occupation of the lake frontage of Chicago by the Illinois Central Railroad. Practically all the water lines operate in the narrow and tortuous Chicago River, impeded by bridges above and until recently by tunnels below. Among other noteworthy cases of railroad control of a city's water front may be mentioned Buffalo, N. Y.; Cleveland, Ohio; Jersey City, N. J.; Norfolk, Va.; Mobile, Ala.; Oakland, Cal.; and Tacoma, Wash.; while at many points along the Ohio and Mississippi rivers the railroads occupy long stretches of water front, including not only the areas needed for their own terminal facilities, but miles of river bank which, but for the adverse possession of the railroads, might readily be acquired and utilized by their would-be competitors by water.

Control of terminal facilities by railroad and industrial interests and steamship lines is so extensive at some ports as to make it difficult for independent boats or occasional sailing vessels to obtain landing privileges. In some cases, for example, a particular navigation line has acquired all of the water front affording direct access to rail terminals, or a number of lines may together control all the conveniently available wharves. At several ports on Long Island Sound the several steamboat lines controlled by the New York, New Haven and Hartford Railroad have acquired possession of the available wharves to such an extent that independent lines and even shippers have experienced great difficulty in obtaining terminals.

It is not necessary, however, for the railroads to own great stretches of water front in order to control the terminal situation at important ports. So far as through traffic is concerned, a railroad need only have a wharf at the point of transfer between rail and water carriers in order to have a decisive advantage over its competitors by water. It is not the wharf alone that gives this advantage; a wharf connecting a rail line and a water line is of much more importance than a wharf without rail connections. Railroads having wharves in such strategic positions commonly "absorb" the wharfage charges in their through rail-and-water rates, or, in other words, make no additional charges for wharfage on through traffic going or coming over their own lines. A water line can not so well afford to offer free wharfage, especially if it has to lease a wharf or pay wharfage charges itself; and in any case, unless the wharf has rail connections, the freight must be taken to and from the wharf either by lighters or by trucks, involving additional expense. Where a railroad comes down to the wharf, lighterage is unnecessary, in the case of goods going over that line at least; and as railroads commonly have switches to many of the important industries along their lines, freight cars can usually be left at the door of the factory, mill, or jobbing house to which it is consigned. Thus, railroad control of terminals results in a decided disadvantage to independent all-water lines, and in procuring the shipment of freight as far as possible by rail, even when it could go partly to its destination by water.

A port which allows its wharves to fall mainly into the hands of railroads is likely to find its local shipping business injured thereby; for railroad control of water terminals at a port apparently tends to result in their use for transfer of through freight between cars and vessels to the exclusion of business originating at or destined to the port itself. A legislative commission recently appointed to investigate conditions at the port of New Orleans, after visiting the ports of Galveston, Mobile, Pensacola, and Savannah, at all of which the terminals are in the hands of railroads and private owners, reported that the shipping business at all these ports is simply a matter of transferring freight from cars to ship; and that the local trade by water of Galveston and Savannah is gone. An extreme case of the use of terminal facilities by a railroad to secure traffic for its line, with the result of creating a monopoly, is that of a pier at Galveston erected by the Southern Pacific Terminal Company (affiliated with the Southern Pacific Railroad) and leased to a shipper of cotton-seed products, one of the conditions of the lease being that the lessee must route all his shipments over the lines of the terminal company. The lease being at a fixed rental per annum, when the lessee's shipments exceed a certain amount a year his terminal charges per hundred pounds were less than the regular wharfage charge to other shippers, and the result was practically to center in him all the cotton-seed product export business of Texas and adjoining States.

The Interstate Commerce Commission has declared this arrangement unlawful in that it gave the lessee undue preference and advantage in exempting him from the published wharfage charges and giving him the exclusive use of wharf space such as other shippers could not obtain. Another way in which railroads controlling wharves have sometimes used them so as to secure undue advantages is by denying their use to independent or competing vessels, even on payment of wharfage charges, while granting their use free of charge to vessels handling traffic in connection with the controlling railroad on through bills of lading, and so bringing traffic to that road. To some extent such discriminations have been declared illegal by the courts, which have held that wharves, at least when they are railroad terminals, are so affected with a public interest that their owners are bound to extend their facilities to all on equal terms, if they hold themselves at all as public wharfingers. This rule, however, will not prevent a railroad owning a wharf from using it solely for its own carrying business in connection with its own lines;[a] nor has it been so universally applied as wholly to do away with the granting of exclusive wharf privileges to steamship lines. At Boston each of the great ocean steamship lines has the exclusive use of a pier belonging to a railroad company; while at Philadelphia the complaint is made that the railroads will not allow lighters to come to their piers, but practically require all the goods coming to their piers to go over their own lines.

There are several ports on the Great Lakes and a few on the Atlantic coast north of Savannah at which the terminals are controlled by railroads and used almost wholly for the transfer of through freight between cars and vessels; but at some of them, especially the smaller places, the question of decay of the local trade has never arisen because the shipping industry has been created by the railroads in connection with their through business. There are advantages both to the railroads and to the general public in the establishment of such transfer terminals at points outside of the large cities, where the price of land is low enough to make plenty of warehouse room feasible, and where, by avoiding the congested city terminals, transfers can be effected with much greater expedition. Congestion of traffic is complained of at many ports as an evil of no small magnitude, and in several cases steps are now being taken by public or private agencies to increase the available wharf facilities.

PUBLIC OWNERSHIP AND CONTROL OF WATER FRONTS AND WHARVES.

Public ownership of wharves is much less common in this country than in Europe, but a number of American cities have owned wharves from early days, and in recent years several cities have more actively undertaken the development of the commercial water front.

Public ownership of the water front alone is not necessarily effective in preventing its practical control by transportation interests. The constitution of the State of Washington provides that the land below the line of high tide shall never be alienated by the State. Yet there is no indication in the data available on this point from the State of Washington that this has prevented the railroads from getting large control of the commercial water fronts; every indication points to extensive railroad control. The ineffectiveness of the Washington system is perhaps due in part to the provision of law which gave riparian owners preference in granting leases of water-front areas, and partly, no doubt, to the provision which limits the rentals to an amount less than the real rental value of such locations.

---

[a] Dutton v. Strong, 1 Black, 23; Indian River Steamboat Company v. East Coast Transportation Company, 28 Fla., 387; West Coast Naval Stores Company v. L. & N. R. R. Co., 121 Fed. Rep., 645.

Even public ownership of wharves and other improvements on the water front is not always effective as a means of retaining actual control. The New York system of partial municipal ownership has been criticised on the ground that by leases of wharves for long terms of years the city practically loses control of important parts of its wharf system, so that vessel owners who neither own nor lease wharves have to obtain landing privileges from the lessees.

Short-term leases are not commonly considered practicable where the lessee is expected to erect expensive improvements, such as fireproof sheds, but provision is sometimes made for compensation for such improvements, after allowing for depreciation. Another plan permitting short leases is the construction of all improvements on public wharves at public expense; though in some cases this may not be financially feasible. San Francisco partly solves this difficulty and also avoids losing actual control of its water front by leasing each new wharf for a short period, never exceeding fifteen years, to such bidder who will take a lease for the smallest number of years, the said bidder to construct at his own expense a wharf of a specified character. At the expiration of the term agreed upon the wharf reverts to the public and becomes a public wharf. On the whole the system seems to have proved satisfactory. At any rate, the public is gradually acquiring valuable wharf properties, practically without expense in the long run. Bond issues are sometimes necessary at San Francisco as elsewhere, for the lessees pay their rentals in annual instalments extending throughout the term of their leases.

COORDINATION OF TERMINAL FACILITIES.

In several of the most important cities of the United States, local shippers are handicapped by lack of convenient access to rail and water transportation facilities, more especially the latter, owing to the haphazard distribution of terminals and the lack of coordination between them. Such disadvantages may more than offset the advantage of nearness to the place of production or sale. Many large cities have belt or terminal railways connecting the trunk railroad terminals; and New Orleans has just completed a public belt railroad connecting both rail and water terminals which is to be operated by public officials. This belt line consists of more than twenty miles of double track, with switches at all the wharves, all the freight depots, and all the more important industries, thus eliminating drayage to the greatest possible extent. A public belt railroad is also operated on the San Francisco water front. Much more common are switching tracks controlled either by a wharf company, as at Galveston and at the Bush terminal in South Brooklyn, or by a trunk railroad, as at Boston. At Philadelphia and Buffalo, however, special precautions have been taken to prevent the terminal railroads connecting the wharves from falling wholly into the control of any single railroad; at Philadelphia, by turning a majority of the stock over to the board of trade and the commercial exchange, as trustees for the commercial interests of the city; and at Buffalo, where the terminal line is owned jointly by two trunk lines, by a franchise requiring equal facilities to be provided for all companies and individuals desiring them.

MECHANICAL LOADING AND UNLOADING APPLIANCES.

Bulk cargoes consisting of such homogeneous materials as coal, ore, or grain lend themselves most readily to mechanical loading and unloading; and it is where such special traffic is greatest in amount that mechanical appliances for loading and unloading vessels find their fullest development. It is said, probably without exaggeration, that no other traffic in the world has arrangements for handling so perfect as has the iron-ore traffic on the Great Lakes and the connecting railroads. Ore trains direct from the mines are run out on high piers or trestles at Duluth and other upper lake ports and unloaded by gravity into pockets from which the ore flows into the steamers alongside the piers. At the ports of discharge on the lower lakes the ore is lifted from the holds of the vessels by electric cranes carrying several tons at a load, and often deposited directly in railroad cars waiting to take it to its destination. Thus vessels carrying over 10,000 tons of ore are often loaded in a few hours, and unloaded in less than a single working day. A vessel often receives its return load of coal without changing its berth, both the loading and the unloading being again effected by mechanical devices. At the coal ports on the Atlantic coast and along the Ohio River and its tributaries coal is loaded mainly by gravity from "tipples" or trestles extending out over the water, while at Cincinnati and New Orleans it is unloaded and elevated to cars or steamships by mechanical means.

Very complete appliances for loading and unloading grain at points of transfer between rail and water lines are provided by the grain elevators, which serve also as storage warehouses for longer or shorter periods, and have machinery for mixing and often for cleaning grain.

The ore trestles at the head of the lakes are owned by the railroads, as are also the receiving appliances at lower lake ports except where industrial concerns are located on the lake front and have their own unloading machines.

Coal tipples in the mining regions are commonly owned by coal-mining companies; those at ports of transshipment, on the Great Lakes and elsewhere, either by coal companies or by railroads; while at distributing points the coal is unloaded mainly at wharves belonging to coal companies, some of which, however, are themselves controlled by railroads.

Grain elevators are owned sometimes by railroads and sometimes by grain dealers. In many cases railroad elevators are leased, and are operated by grain dealers as lessees. At Buffalo there is an elevator pool composed of the elevators having both rail and water connections, except those belonging to railroad companies, which latter were active in its organization, but were forced out by the amendment to the interstate commerce act extending to terminal facilities the prohibition against pooling. The railroads still act in harmony with the pool, however, and there seem to be good reasons for believing that the pool is really an agency through which the railroads practically control the elevator situation at Buffalo.

At New Orleans the United Fruit Company has several machines for unloading bananas from its vessels by means of endless canvas belts, consisting of a series of pockets, which can also be employed in loading or unloading any merchandise put up in sacks or small packages.

In marked contrast with the complete arrangements provided by railroads, coal companies, and other concerns for handling ore, coal, grain, and tropical fruits, is the almost complete lack of mechanical appliances for loading and unloading cargoes of general merchandise at American ports, whether the wharves are under railroad, private, or public control. In loading or unloading a large general cargo, the vessel's own steam winches are employed, together with skids, to deposit the freight on the wharf at the vessel's side or to lift it from that point into the vessel's hold; but the movement of freight on the wharf itself is usually effected with hand trucks. At European ports it is common to find the wharves equipped with powerful cranes moving on tracks paralleling the water's edge, so they can be brought into requisition at any point. There is an obvious advantage in the use of such machinery on the wharf instead of the vessel's own winches, because the wharf machinery has a longer reach landward, and can be used in loading railroad cars direct from the vessel or in storing freight in a warehouse. That American stevedores are content to do with comparatively primitive arrangements is one of the most curious facts connected with American shipping.

Along the Ohio River the rise and fall of the water is too great to admit of the use of fixed wharves, and their place is therefore taken by floating wharf boats which rise and fall with the water. To the inconvenience of this kind of landing is added, at most points, the difficulty of hauling freight up the steep banks of the river. The same is true of some places on the lower Mississippi.

PORT CHARGES.

At New York and some other ports complaints of high port charges are frequently heard. At New York, indeed, the decline of commerce of the port is attributed largely to the high charges for pilotage, towboat charges, wharfage, lighterage, and the expense of discharging cargo. The United States tonnage tax on vessels from foreign ports, together with custom-house and quarantine charges, and the local health officer's and port warden's fees, make up the other port charges, commonly so called. It is difficult to keep wharfage charges low where land, and consequently wharf room, is as valuable as it is on Manhattan Island.

Where the wharves are publicly owned, as a rule, they are not made a source of revenue to any considerable extent, the usual policy, in theory at least, being to reduce the wharfage charges to a point which will yield only enough revenue to pay for the maintenance of the water front and to pay the interest on the investment in improvements. Where the wharves are privately owned, the maximum wharfage rates are sometimes prescribed by law or municipal ordinance in order to prevent extortion; but the lowest charges, considering the facilities furnished, seem to be found, as a rule, where the wharves are publicly owned. Thus at San Francisco the wharfage charges are unusually low, being only 5 cents per ton for grain and general merchandise, which at some other ports pay 25 cents and even 50 cents per ton. At Seattle a comparison of the charges at the municipal and other wharves shows similar contrasts; thus the rate for lumber is 15 cents per M at the municipal wharf, as compared with 50 cents to $1 per M at other wharves.

The importance of wharfage charges is indicated by the statement of the traffic manager of the Pittsburg Chamber of Commerce, to the effect that excessive charges along the Ohio River offset the lower rates of water transportation as compared with rail transportation, and in the case of small towns cause the steamboats to pass by without landing at all, depriving these places of the benefit of water competition.

COMPULSORY PILOTAGE.

The employment of a pilot and payment of pilotage by vessels entering a seaport has commonly been made compulsory by state laws, in order to insure the presence of a sufficient number of skilled pilots to serve all vessels; but vessels engaged in the coasting trade only are now commonly exempted from the requirement of compulsory pilotage. In several of the South Atlantic States, however, sailing vessels in the coasting trade are still required to pay pilotage fees.

A large proportion of the sailing interests reporting to the Bureau of Corporations from the Atlantic coast complain of compulsory pilotage as an unjust discrimination against sailing vessels. Before entering the harbors and navigating the rivers of the several States south of Virginia on the Atlantic coast, sailing vessels are required by state laws to employ local pilots, or to pay the prescribed pilotage fee to the first pilot offering his services, whether he is actually employed or not. Formerly steamers were also subject to this requirement; but the difficulties of navigation which originally justified compulsory pilotage having been gradually removed by river and harbor improvements, steam vessels engaged in the coasting trade were freed from the requirement by act of Congress in 1871. Bills have repeatedly been introduced in Congress for the relief of sailing vessels from this burden, but they have failed of enactment.

Sailing interests maintain that sailing vessels can be as safely navigated on the waters of Southern harbors as can steam vessels.

Coasting vessels were exempted from compulsory pilotage in Virginia waters by the state legislature of 1908.

PART IV.—RAIL RATES AND WATER RATES, INCLUDING THEIR RECIPROCAL INFLUENCES.

GENERAL CONSIDERATIONS.

Water rates are usually more competitive than rail rates, mainly for the reason that water transportation requires practically no outlay for right of way and much less outlay for terminals than in the case of railroads. Operating costs of water lines therefore constitute a much larger proportion of the entire cost of transportation, and fixed charges are much lower.

Railroads have developed far more fully than water lines the system of freight classifications, there being at present three general rail freight classifications in the country, the Official, Western, and Southern. Some water lines operating jointly with rail lines have, however, adopted these classifications, or modifications of them. Traffic associations for the making of joint rates are much more common with railroads than with waterways. Unlike interstate rail rates, interstate water rates per se need not be filed or made public.

LONG-DISTANCE TRAFFIC.

The most striking characteristic of the American railroad rate system has been the extreme development of the long-distance traffic by means of relatively low rates. It is true that in many instances a tariff is used, somewhat approaching a "distance tariff," with rates proportioned roughly to the length of the haul, but the exceptions to the distance tariff principle are extremely common, and in fact the general tendency has been toward another principle, that of a wholesale rate. Railroads have given low rates for large long-distance traffic between important markets. There has been an extreme effort on their part to equalize different producing districts in the same market, regardless of differences in distance, and thus to make, to a certain extent, the producers of a given commodity all over the country competitors in all markets. This has resulted in a system of long-distance traffic and long haul peculiar to the United States.

This has had a marked effect on the waterway system. The business of the country has thus been adjusted to long-distance transportation, while our waterway system is mainly an aggregation of separate units of widely differing physical characteristics. It is therefore far less adapted for continuous through traffic that are the railroads. It is thus unable to meet the demands of modern business as developed by the railroad. In comparing, therefore, European water systems with our own waterways this difference must be borne in mind and we must recognize the peculiar demand which is made in this country upon our entire transportation system, including the waterways, and the peculiar difficulty which our waterways here have therefore to meet.

PRORATING.

The above considerations involve the question of the prorating between railroads and waterways. The railroads have exercised a marked effect over waterways by refusal to prorate with them in many cases, and especially with rivers and canals, although prorating is practically the rule among railroads. To give an example of prorating, a railroad, for instance, from New York to Chicago will join with a railroad from Chicago to San Francisco in making a through rate from coast to coast which is lower than would be the sum of the two local rates New York to Chicago and Chicago to San Francisco. This is called prorating. It is simply the making of the two roads one for the purposes of the agreement and applying to that joint route the well-known long-distance principle of a relatively lower charge for a longer distance. But in the case of rivers the railroads very rarely make any such lower through rates. The shipper in such cases sending his freight partly by rail and partly by water must pay the full rail rate to the water terminus, and then the full water rate to destination; that is to say, the sum of the two local rates. The railroad does not join with the waterway in making a through rate less than this sum and dividing this low rate between them. This, of course, tends to make the rates for an all-rail haul relatively lower than for the same distance by rail and water, because it applies to the all-rail haul the long-distance principle, while the rail-and-water rate covering the same entire distance is governed by the principle of short-distance shipments, which always take a higher rate per ton per mile.

Now, inasmuch as all shipments of importance for any considerable distance must go at least in part by rail, it is obvious that this power of the railroads to refuse to prorate with the water carrier is a very effective weapon in preventing shipments by water. Such failure to prorate is especially frequent and especially effective on the waterways of the Mississippi Valley. So far as present information goes, there are no such rail-and-water prorating arrangements in effect on the Mississippi below St. Louis, except at certain points on the Black River and to certain points in Louisiana not reached by rail. When prorating does appear as between rail and river lines, it is usually to points of minor importance or where without such rail-and-water arrangement the railroad could do no business at all.

It is true that in some cases the water lines have themselves preferred not to prorate with railroads, lest the water lines should by such "joint arrangement" make themselves subject to the special provisions of the interstate commerce act.

This power over prorating is also frequently used by the railroads in another way—that is to say, not to prevent shipments by water, but to send rail-and-water shipments over a certain favored water line, usually affiliated with or controlled by the railroad. It does this by exclusively prorating with that line.

That is to say, in brief, the railroads of the country, by refusal to prorate, can, and in large measure do, prevent the rivers and canals from becoming a part of the whole transportation system of the United States, or else they thus extend their control over the waterway system by prorating only with favored affiliated water lines. It follows, necessarily, that the water line thus favored will, other things being equal, overcome water lines not so favored.

COMPARISONS OF RAIL AND WATER RATES—ATLANTIC AND GULF COASTS.

Coastwise all-water rates on coal are much lower than rail rates as between coast points. To interior points, however, the railroads compete with the water routes. The same is true of lumber. Water rates on cotton between coast points are much below the rail rates. The all-water rate from Galveston to Boston in 1907 was 40 cents, while the all-rail rate was 97 cents. It should be noted, however, that local water routes along the coast and its tributary rivers do not show rates much lower than rail, thus differing from the long-distance movement.

CANAL RATES.

Any comparison here is extremely difficult by reason of the confusing variety of tolls, lockage and towage charges, and also the difference in service. In general, canal rates show little advantage over rail rates. The inland route, however, between Philadelphia and Albemarle Sound by way of the Chesapeake and Delaware and other connecting canals has rates on coal and lumber considerably less than the all-rail rates.

GREAT LAKES.

In the through bulk movement of iron ore and coal between the upper lakes and Lake Erie, the advantage of the lake routes is so decisive that there is practically no rail competition. In the grain movement from Lake Michigan there has been active competition, and the rail rate varies accordingly, dropping in the summer during the season of navigation, and rising in the winter.

Water rates on lumber between lake points are lower than all-rail rates. The water rate Duluth to Chicago, 1907, was $2.50 per thousand feet; all-rail rate, about $4. But, again, as soon as interior points are considered, the advantage of the lake route declines. On through package freight the class rates by lake and rail and by canal and lake are regularly lower than the all-rail rates. From New York to Chicago the standard all-rail rate on class 1 is 75 cents; joint rail-and-lake rate, 62 cents; canal-and-lake rate, 42 cents. The differentials, however, are much less to interior points beyond the lake terminals.

MISSISSIPPI VALLEY.

The notable decline in traffic on the rivers of the Mississippi Valley, except that in lumber and coal, indicates clearly that the freight rates of the regular river lines, in connection with other expenses, offer little or no advantage to the shipper over railway rates. The coal traffic is perhaps the exception that proves the rule; and, as pointed out in a previous part of this discussion, it is of a unique character. The cost of transportation by river on coal from Pittsburg to Cincinnati is about 74 cents a ton, while the rail rate is $1.35; but this traffic is almost entirely confined to points along the river, because the railroads make such high local rates for river coal when shipped back from the river.

Similarly, logs and lumber are exceptional, because very little equipment is required to move them. An exact statement of the cost of raft transportation is impossible. One sawmill company estimates that it costs about 50 cents per thousand feet to float logs down the rivers in West Virginia, make up rafts, and tow the rafts to Cincinnati. The corresponding railroad rate is about $4.50 per thousand feet.

Class rates on freight moving between river points on the Ohio and Mississippi rivers and tributaries are usually less than the rail rates on the same traffic. Against these lower rates, however, must be considered the cost of marine insurance and terminal charges. The net result in most cases does not allow much differential in favor of the river. The river rates between St. Louis and Keokuk are about 20 per cent less than the all-rail rates. On cotton from river points below Memphis to that city the rail rate has been $1.25 per bale, river rate 75 cents, but to the river rate must be added 20 cents a bale for insurance and 25 cents for drayage in Memphis, and often the cost of a longer haul to the point of original shipment.

PACIFIC COAST.

There is here a large coastwise movement of lumber with little rail competition. The rates fluctuate more or less. On traffic generally the influence of ocean competition is shown in the relatively lower rail rates between coast points than to inland points in the same territory. Rail rates from San Francisco to Ashland, Oreg. (an interior point), are twice to three times as much as are the rail rates to Portland, a much greater distance.

On local bay and river routes the railroads operate or control boat lines competing actively with independent boat lines. Rail rates to competitive points are thus in most cases reduced to the level of water rates, while to nonwater points at corresponding distances rail rates are much higher. These conditions appear on the rivers tributary to San Francisco Bay and on Columbia River and Puget Sound. Both rail and water rates along the Columbia River were reduced after the opening of the canal around the Cascades in 1895.

TRANSCONTINENTAL RATES.

The effect of water competition on transcontinental freight rates is quite marked. In general, class rates from New York to the Pacific coast via the Panama route are from 20 to 42 per cent lower than the all-rail rates. Rail rates to intermediate points slightly east of the Pacific coast are frequently determined by the rates to the coast plus the local rate back from the coast, these being among the marked exceptions to the principle of the long and short haul clause.

COMPETITIVE METHODS OF RAILROADS.

The power of granting or refusing prorating arrangements has already been noted as a most effective means of competition. Railroad control of strategic terminal facilities, and especially transfer points, is also an important factor.

Where water lines are weak, railroads have frequently engaged in destructive competition, making rates to competitive points along the waterway lower than rates covering similar distances inland. This has involved a number of interpretations of the so-called long and short haul clause of the interstate commerce act. This clause substantially prohibits the charging of "a greater compensation * * * for the transportation * * * under substantially similar circumstances and conditions for a shorter than for a longer distance over the same line in the same direction, the shorter being included within the longer distance." The words "substantially similar circumstances," however, have been so broadly construed as to take away largely the effect of the section. The United States Supreme Court, on a review of the decision of the Interstate Commerce Commission in the Alabama Midland case (168 U. S. 144; 1897), cited the possibility of potential water competition in connection with the competition of other railroads and trade centers, as a factor in establishing circumstances that were not "substantially similar," and to be lawfully considered in making railroad rates.

The result has been that the railroads have continued to reduce rates at many points where water competition occurs, while they may recoup themselves at inland points and thus, at no net loss to themselves, greatly injure the water-borne traffic. This is shown by a comparison of the railroad rates from points along the Mississippi to New Orleans with the rates from points inland at the same distance from New Orleans, the inland rates being in almost all cases much higher. Rail rates from New Orleans to Bayou Sara, on the river, average about 16 cents per hundred pounds less than to Hattiesburg, a shorter distance; to Greenville the rates average about 16 cents less than to Rolling Fork, Miss., a shorter distance; to Memphis the rates average about 17 cents lower than to Mount Vernon, which is less than half the distance.

Certain broad results of rail and water competition are illustrated in the following specific instances:

(*a*) That of the so-called Southeastern Differential Territory, a wide strip on the South Atlantic coast reaching inland several hundred miles. There is a strong waterway traffic from the North to the South Atlantic coast. Accordingly in this case the railroads have conceded this "differential territory," in a way, to the water lines. That is to say, there exists a general arrangement of long standing that the rates, for instance, from New York to Charleston by water, plus the rates by rail from Charleston inland, within the limits of this territory, shall be less than the all-rail rate from New York to the point of final destination. This differential in favor of the waterways, of course, tends to give them traffic within this territory.

This is evidently a case where there is strong water competition, and the railroads have been obliged to concede a share of the traffic to it. In this case also, however, the railroads have used another method, namely, that of absorbing the chief water lines. Most of the important coastwise lines running down the South Atlantic coast are controlled by or closely affiliated with important railway systems.

(*b*) The Great Lakes. This is another case of strong water competition. Here the railroads have used the latter method, namely, that of absorption or control, many of the important packet lines on the Lakes being owned or controlled by the trunk line railroads.

(*c*) The Pacific coast. Here the railroads have again used the latter method. Most of the important steamer lines, both ocean and local, are controlled by railroads.

(*d*) The Mississippi Valley. This is a case of a comparatively weak waterway, and its competition has been met by destructive competition on the part of the railroads, by the lowering of rates to competitive water points and the taking away of most of the former river traffic, so that it is now in a condition of extreme decline. The railroads have also in many cases succeeded in shutting in the Mississippi traffic—as, for instance, the coal business—practically to the banks of the river.

EFFECT OF WATERWAYS ON RAILROADS.

It is a curious fact that the ordinary inland waterway seems to be more potential in causing the reduction of railroad rates than in securing traffic for itself, though there is a marked difference between waterways in this respect, and any consideration of them must keep in mind these variations, and great care be taken in deducing general conclusions from the conditions of one class of water routes.

Rates on cotton from interior shipping points show the influence of water competition in lower rail rates from river points such as Vicksburg and Augusta, as compared with nonriver points such as Jackson, Miss., and Atlanta. The rail rate from Charleston to Jacksonville is lower than from Savannah to Augusta, though the latter distance is only one-half the former. The lake rate Chicago to Sheboygan on class 1 is 27 cents and the rail rate 30, while to interior points at similar distances the rail rates are higher—to Fond du Lac 40 cents and to Oshkosh 43 cents.

Innumerable instances might be cited of the effect of water routes on rail rates. The foregoing are merely examples of a large class.

SCOPE OF THE EFFECTS OF WATERWAY COMPETITION.

It is an important fact that the effect of water competition on rail rates is much broader than would at first be expected, by reason of certain outside circumstances. These are the effect of competing markets, competing railroads, and the interdependence of railroad rates generally. An example may be stated as follows: Suppose that there is a rail rate from St. Louis to New Orleans on a given commodity of 40 cents a hundred pounds. Suppose also a similar rate exists on the same commodity from Chicago to New Orleans. Suppose, now, river competition between St. Louis and New Orleans arises suddenly and the St. Louis-New Orleans railroad is obliged to reduce its rate to New Orleans to 30 cents to meet this new river competition. Immediately the other railroad running between Chicago and New Orleans is met with a demand by its Chicago shippers that its rate also be reduced to 30 cents to New Orleans, in order to put Chicago producers of that commodity on a par with St. Louis producers in the New Orleans market. The Chicago-New Orleans road, therefore, having no interest in St. Louis, but being interested in the traffic from Chicago, is under strong inducement to make a similar reduction to 30 cents. Furthermore, if this be done the other connections of the Chicago-New Orleans road will be affected by the change, as will also its immediate competitors from other markets competing with New Orleans. Finally, the numerou rate agreements, which often involve adjustments of rates over extensive areas, will also be affected by this change, so that the entir effect of the original river competition may thus be very greatly broadened.

CONCLUSIONS.

It will thus be seen that any consideration of the waterway question must first take account of its relations with the rail system The two are inevitably part of a general transportation system. S long as the two are run in opposition the waterways will inevitably suffer by reason of their lack of adaptation to modern transportatio demands. It is almost axiomatic that our waterways can not carr their reasonable proportion of the country's traffic, nor can their business ever be equal to their reasonable possibilities unless th present destructive competition with the rail system can in some wa be modified and the two systems be made to cooperate.

GROWTH OF INTERNAL AND FOREIGN COMMERCE.

By O. P. Austin,

Chief of the Bureau of Statistics, Department of Commerce and Labor.

Conservation and commerce are so closely allied and the latter, commerce, so much affected by the application of the former, conservation, that a very few words on commerce may not be inappropriate to this discussion of conservation. This seems particularly true in case the discussion should relate especially to internal commerce, or the exchanges of our own people among themselves. True, the foreign commerce of the United States has grown from $300,000,000 in 1850 to $3,000,000,000 in the fiscal year 1908, being to-day practically ten times as much as in 1850; while population meantime was growing from 23,000,000 to 86,000,000, the per capita foreign commerce thus being $13.71 in 1850 and in the fiscal year 1908, $34.74, an increase of about 150 per cent in the per capita value of our foreign commerce. In internal commerce, however, which seems more closely related to the question of conservation, perhaps because of its greater importance than the foreign commerce and of its closer relation to the people in their every-day life—in internal commerce the growth has been much greater, the internal commerce of the United States having been valued at $2,000,000,000 in 1850 and over $28,000,000,000 in 1907, being thus practically fourteen times as much in 1907 as in 1850; while the per capita value of the internal commerce, which in 1850 was $86, was in 1907, $315. Thus, while foreign commerce is to-day ten times as much as in 1850, internal commerce is fourteen times as much as at that period; and the per capita of the foreign commerce is now practically three times as great as in 1850, while the per capita value of the internal commerce is now practically four times as much as in 1850. The internal commerce of the United States, including in this term merely a single transaction in all the merchandise forming the exchanges among our own people, was in 1850 practically seven times as great as the entire foreign commerce, and in 1907 was nine times as great as the entire foreign commerce, and equaled in value all of the imports plus all of the exports of every nation of the world.

The measurement of the internal commerce of the United States is arrived at by a process entirely different from that by which the foreign commerce is measured. In determining the value of the foreign commerce, we require from every importer and every exporter a statement of the true value of the merchandise which he is importing or exporting, and aggregating these imports of all ports and exports of all ports we get the grand total of our foreign trade, which in the fiscal year 1908 aggregated, as already indicated, $3,000,000,000, against a little more than $300,000,000 in 1850. To measure the internal commerce of the country is more difficult, however, since there are no gateways through which it passes and at which a statement of its value may be required. It is possible, however, by a different process to determine the value of the merchandise which passes from hand to hand for consumption within the United States; and as statements of foreign commerce include merely the value of the articles comprising it, the measurement of the internal commerce by a statement of the value of the articles which it includes, and thus of a single transaction in those articles, seems to be a logical and fair one, We may, therefore, assume that if we can determine the value of the articles which form the internal commerce the measurement may at least approximate in accuracy the measurement of the foreign commerce to which we are more accustomed.

Fortunately, we are able to determine at certain dates in our national history the value of at least the principal articles entering the internal commerce of the country. The census shows the value of manufactures, of agricultural products, the products of the mines, the fisheries; and the record of imports shows the value of merchandise brought in from foreign countries and subsequently entering the internal commerce. By aggregating these stated values at the place of production of the principal articles entering the internal commerce of the country and adding a reasonable sum as the probable cost of transporting them to the consumer, we may at least approximate the value of the merchandise consumed among our own people, a single transaction in which may be properly accepted as a measurement of the value of the internal commerce. The census of 1900 showed the value of manufactures in the United States to be $13,000,000,000; of products of agriculture, practically $4,000,000,000; and of minerals, about $1,000,000,000. The importations of 1900 were practically $1,000,000,000 in value. Adding to these the products of the forests and fisheries and the increased value of all products due to transportation from the place of production to the purchaser, we may fairly set down the value of the internal commerce of the country as measured by a single transaction in those articles at $20,000,000,000 in the year 1900.

Applying this method to earlier and more recent years, I find that the value of the internal commerce of the country may be reasonably estimated at $2,000,000,000 in 1850, $3,500,000,000 in 1860, $5,000,000,000 in 1870 (gold value), $7,750,000,000 in 1880, $12,000,000,000 in 1890, $20,000,000,000 in 1900, and $28,000,000,000 in 1907, the last named year being estimated upon the census figures of manufactures for 1905, the Agricultural Department's estimate of the value of farm products in 1907, the Geological Survey estimate of the value of mineral products, and the stated value of imports of that year. Comparing these with the census figures of population, we get the per capita value of the internal commerce in 1850, $86; in 1860, $111; in 1870, $132; in 1880, $154; in 1890, $192; in 1900, $261; and in 1907, $326. Meantime the per capita wealth has grown, according to the census figures, from $307 in 1850 to $514 in 1860; $780 in 1870; $850 in 1880; $1,039 in 1890; $1,165 in 1900; and $1,310 in 1904, the latest year for which estimates have been made, the increase in per capita wealth having been slightly greater than the increase in per capita of internal commerce.

$\frac{300}{9000}$ $\frac{3}{28000}$ [illegible]

IRRIGATION.

By F. H. Newell,
Director United States Reclamation Service.

The National Government has passed three important laws for the encouragement of irrigation; (*a*) The desert land law, which was best adapted to individual enterprise in the development of comparatively small tracts of land by irrigation systems of moderate size; (*b*) The Carey act, which was designed to encourage corporate irrigation of public land under state auspices; (*c*) the reclamation act, which provides for construction of irrigation works by the National Government itself. Enumeration was made by the United States census of the acreage irrigated in 1889, 1899, and 1902. With those figures as a guide, and by the use of the general information possessed by the Reclamation Service, an estimate has been made of the acreage irrigated in 1907. The results given in the following table include very large areas which receive only one or two irrigations by flood water, and others where the supply is inadequate.

Irrigation in the United States.

NUMBER OF FARMS IRRIGATED.

Year.	United States.	Arid region.	Semiarid region.	Rice region.
1907	[a] 167,200	152,000	7,800	7,400
1902	133,356	122,156	7,021	4,179
1899	110,117	102,819	4,897	2,401
1889	54,136	52,584	1,552	....

[a] Estimated.

NUMBER OF ACRES IRRIGATED.

1907	[a] 11,000,000	9,700,000	425,000	876,000
1902	9,681,280	8,471,641	405,440	600,199
1899	7,778,904	7,963,273	266,417	251,214
1889	3,631,381	3,564,416	66,965	....

[a] Estimated.

Irrigation by individual effort has been undertaken in each instance in a small way, but in the aggregate this method has led to the most important development and has resulted in the largest total acreage. It is also being developed to some extent by corporate enterprise, but results from this source are relatively meager, except where the corporations are of a community character. Cooperative communities have done much in the past and their future works will probably be important. Development by States under the provisions of the "Carey Act" promises well in some localities where there is efficient state supervision, as in Idaho, Wyoming, and Oregon; large results have already been accomplished in the first-named State. National development through the agency of the Reclamation Act is beginning to show results and is steadily proceeding. It has been confined mainly to those enterprises which are too large, too costly, or too slow in producing returns to tempt private or corporate investments.

The Reclamation Service has 29 projects in various stages of construction; these contemplate the ultimate irrigation of 2,700,000 acres, against a total acreage of 367,023 for which water was furnished in 1908. The following table shows the distribution of the projects, the total ultimate irrigable area under each, and the irrigated areas for 1908 and 1909:

Irrigation projects.

State.	Project.	Irrigable area.	Irrigated 1908.
		Acres.	*Acres.*
Arizona	Salt River	272,000	115,000
California	Orland	14,000	.....
California-Arizona	Yuma	92,000	3,800
Colorado	Grand Valley	62,000	.....
	Uncompahgre	147,000	15,600
Idaho	Minidoka	74,000	24,464
	Payette-Boise	315,000	55,000
Kansas	Garden City	8,500	5,558
Montana	Huntley	28,000	4,400
	St. Mary	.....	.....
	Sun River	256,000	.....
Nebraska-Wyoming	North Platte	164,000	23,220
Nevada	Truckee-Carson	200,000	27,450
New Mexico	Carlsbad	20,000	8,000
	Hondo	10,000	1,500
	Rio Grande	180,000	17,000
North Dakota	Buford-Trenton	12,500	1,200
	Williston	12,000	2,000
North Dakota-Montana	Yellowstone	66,000	.....
Oklahoma	Cimarron	.....	.....
Oregon	Umatilla	20,000	2,500
Oregon-California	Klamath	187,000	9,378
South Dakota	Belle Fourche	100,000	5,000
Utah	Strawberry	60,000	.....
Washington	Okanogan	10,000	1,353
	Sunnyside	90,000	42,000
	Tieton	30,000	.....
	Wapato	120,000	.....
Wyoming	Shoshone	150,000	2,600
		2,700,000	367,023

Under the Carey Act there have been approved 1,716,424 acres for construction, and patents have been granted covering 293,083 acres.

The following table shows the location of the lands being irrigated under this act:

Segregations applied for under the act of August 18, 1894 (28 Stat. L., 372–422), and the acts amendatory thereof, with the action taken thereon, from the passage of the act to July 1, 1908.

[Areas in acres.]

State.	Selected.	Rejected, relinquished, etc.	Approved, not patented.	Approved and patented.
Colorado	59,807.94	5,704.95	54,102.99	.....
Idaho	1,180,566.17	265,828.94	662,254.00	156,954.90
Montana	104,587.98	2,792.53	83,498.54	18,296.91
Nevada	12,644.61	8,000.00	.....	.....
Oregon	432,202.53	78,507.31	245,287.52	50,063.13
Utah	328,327.40	236,980.83	48,226.74	.....
Washington	155,649.39	155,649.39	.....	.....
Wyoming	965,508.64	198,994.18	623,054.44	67,768.72
Total	3,239,384.66	952,458.13	1,716,424.23	293,083.66

Oregon segregation list No. 5, covering 58,344.57 acres, is now pending before the Secretary on appeal from the decision of the General Land Office rejecting it.

Wyoming segregation list No. 27, covering 26,936.03 acres, was rejected by the General Land Office, which decision was affirmed by the department, but said decision has not yet become final.

Irrigation under the Indian Service is rapidly increasing.

The extent to which the irrigated area in the arid and semiarid regions can be increased can not be accurately estimated with present knowledge. If all the run-off waters of the arid region could be conserved and employed in irrigation, the total area might, perhaps, be brought to nearly 60,000,000 acres. This is very uncertain, however, as our knowledge of run-off is confined to only a portion of the streams, and is incomplete; furthermore, such an estimate involves assumptions regarding the duty of water that may introduce large errors.

It is known, however, that large portions of the water of the arid region can not be used in irrigation, as no irrigable land exists upon which it can be brought at feasible cost. In general, it may be stated that the value of irrigated land is increasing, and certain developments are tending to decrease costs of construction, so that it is impossible to draw any approximate line of demarkation, even if we had full knowledge regarding present costs. This would require elaborate surveys, which have not been made. For these reasons any present estimate of the total irrigable area would necessarily be little better than a guess. With present data, the closest statement is probably between 40,000,000 and 50,000,000 acres, including that now under ditch.

The subjects of irrigation, forestry, navigation, power, domestic water supply, and drainage are all closely interrelated and should be thoroughly studied together, not only in the arid but in the humid regions. No one of these questions can be properly treated without full regard to all the others. Proper study of these comprehensive questions should include more extended observations of rainfall and evaporation, especially in high altitudes, and of the annual flow of all streams. Comprehensive topographic maps should be made showing the areas of drainage basins, the location of reservoir sites, and their relation in altitude and location to irrigable lands and to power and navigation resources. Such maps are the basic information most urgently needed for all land classification, and without them no wise policy can be adopted.

Water laws.

Both state and national laws are incomplete in permitting and encouraging the settlement and improvement of lands which should be reserved for reservoir sites. Thorough surveys should be made and all feasible reservoir sites discovered and reserved for development.

The present laws in some States tend to promote irrigation, but in others they do not. The most primitive form of regulation of the use of water in irrigation is best exemplified by the present laws of the State of California. These declare the principles of priority and beneficial use, and provide that claims to the use of water shall be recorded in the form of a notice of appropriation, and shall be perfected by application to a beneficial use. At the same time they try to recognize as concurrent on the same stream rights derived by prior appropriation and rights depending on riparian ownership. The riparian doctrine of water rights should be definitely and permanently abrogated in all arid regions. This has been done in some States by constitutional provision and in some by judicial decision. In all the States of the arid region where the riparian doctrine is recognized, material modifications in the old common-law doctrine have been made and put into effect.

The form and theory of these laws have been developed by several of the States, elaborating upon the principles of the California laws and the methods established in that State.

The operation of the earlier forms of these laws places no restraint upon appropriations of water. The courts in passing upon the claims of the appropriators, having scant information concerning the amount of water available for use, with no guide to the quantities which should be applied in the cultivation of crops, and confronted with the excessive claims of the parties, have often adjudicated rights to the use of water many times in excess of the amount carried by the stream.

The knowledge obtained during recent years concerning the discharge of streams and the use of water has caused such decrees to become exceptional in present practice. Nevertheless, the need for a more careful regulation of the appropriation and use of water has been apparent for many years.

In 1890 the State of Wyoming enacted a code of water laws providing for supervision of the utilization of the water supply through a state engineer and state board of control who adjudicate rights to the use of water in the first instance. The division superintendents and water masters have immediate charge of the distribution of the water in the various water divisions.

Nebraska subsequently adopted a code of water laws similar to the laws of Wyoming.

Idaho, Utah, and Nevada in 1903 adopted codes of water laws based upon those of Wyoming with, however, a number of important modifications dictated by experience and the development of irrigation practice.

At the sessions of the legislatures of Oregon and Washington in 1903, the governors were directed to appoint commissions to prepare and submit drafts of a code of irrigation law.

At a joint session of the two commissions with the then chief engineer and other members of the Reclamation Service held in August, 1904, the fundamental principles of a modern irrigation code were discussed. There was also some consideration of the provisions which should be incorporated in such a code to facilitate the operations of the Federal Government in carrying on the work of constructing the irrigation systems contemplated by the act of Congress approved June 17, 1902 (32 Stat., 388), known as the Reclamation Act.

After this meeting, a state code of water laws was drafted by Mr. Morris Bien, supervising engineer of the United States Reclamation Service, which, in 1905, was adopted without material change by the legislatures of North Dakota, South Dakota, and Oklahoma. The legislatures of Oregon, Washington, and New Mexico adopted parts of this code, but omitted some of the most important features. This code does not involve any new principles, but constitutes a revision and combination of the features of the more modern statutes, arranged as a consistent and complete code.

Proposed water code.

A state code of water laws should provide for the appropriation, adjudication, and apportionment of the waters of the State, and divides itself naturally into four branches.

First. A declaration of the fundamental principles upon which the right to use water shall be based.

Second. The adjudication of rights to the use of water claimed under the previous laws, thus determining the unappropriated public waters.

Third. The regulation, control, and determination of the rights to water to be subsequently acquired.

Fourth. The regulation and control of the distribution of water, rights to the use of which have been established.

The code under discussion is arranged to provide appropriate procedure for the application of these principles.

Under the first heading the fundamental principles are few and well established, namely, that all the waters within the limits of the State belong to the public and are subject to appropriation for beneficial use, except from sources of supply which are navigable; that the prior appropriation of water shall be the basis, and beneficial use the measure and the limit of the right; that the use of water is a public use, and private parties may exercise the right of eminent domain for the utilization thereof; and that water used for irrigation shall be appurtenant to the land on which it is used.

Under the second heading, providing for the adjudication of rights claimed under prior laws, it is now generally conceded that the final adjudication must be by the courts. The codes of the different States contemplate various forms of procedure. In the code referred to, a state engineer, appointed for six years by the governor subject to confirmation by the Senate, is to make a complete hydrographic survey of a stream system, obtaining all the data necessary to determine the amount of water available and the rights of the parties entitled to the use of it. This material is turned over to the attorney-general of the State, who is required to enter suit promptly for the determination of the rights of all parties and to prosecute the same diligently to a conclusion. In all suits for the determination of the right to the use of the waters of any stream system, all who claim the right to use such waters shall be made parties. In all suits involving the determination of water rights, the attorney-general is required to intervene on behalf of the State, if in the opinion of the state engineer the public interest requires it.

The third subject, namely, that of the regulation, control, and determination of rights to the use of water to be acquired, is placed in the hands of the state engineer. The procedure proposed is substantially the same as that adopted in the other States having a modern irrigation code with some differences of detail.

The principal feature to be noticed is that before any work looking to the construction of an irrigable system is commenced, and after the state engineer has passed upon the form and substance of the application, the intention to appropriate the water shall be published in a newspaper circulated in the community. After such publication the state engineer will approve the application if no valid objection is presented.

When the construction is completed, the works are to be inspected and approved by the state engineer, who will then determine their capacity, which will limit the amount of the appropriation. Afterwards when the water is applied to a beneficial use, the state engineer makes a further inspection, whereupon he issues a license for the appropriation of the amount of water which has been applied to a beneficial use. A time limit is fixed for completion of construction and for beneficial use.

For the distribution of the water, which comes under the fourth branch, the States are divided by the law into water divisions by drainage areas, each under the supervision of a water commissioner appointed by the supreme court of the State. Their function being the distribution of water under judicial decree or appropriation, they may be regarded as, in a sense, officers of the court. The water commissioners with the state engineer constitute a board of water commissioners, of which the latter is president. The water commissioners each serve six years, their terms being so arranged that a new one is appointed every two years. This board has general supervision over the waters of the State.

The actual work of distributing the waters to those entitled to use them is performed by water masters appointed by the water commissioners with the approval of the state engineer. Each water master has charge of a water district set apart by the state engineer, as found necessary from time to time. The operations of the water master are under the supervision of the water commissioner, and their acts are subject to appeal to the state engineer.

The cost of the water distribution is borne by the water users. The general expenses of the state engineer and the water commissioners are paid by the State. The greater part, if not all, of this expense will be returned to the state treasury by the fees collected by the state engineer and by the repayment of the cost of hydrographic surveys by the parties to the suits for adjudication.

Special reference should also be made to the features of the draft relating to the work under the federal Reclamation Act.

In order that the State may obtain the full benefit of this work and to prevent serious interference with, and perhaps the entire abandonment of, the projects which are considered for investigation, it is provided that the water supply for such projects shall be reserved from general appropriation until the investigations of the Reclamation Service shall determine the precise amount required for the project, the remainder being then released from such reservation.

It is also provided that state lands coming under such project shall be disposed of in harmony with the plans for the disposition of the lands of the United States, and that lands required for the reclamation project for irrigation works shall be transferred to the United States without charge.

In all sales of state lands after the enactment of the code, the conveyance is to reserve right of way for ditches or canals constructed by authority of the United States.

The theory of these provisions is that the State regulates the appropriation of the water, exercising this power and holding the land in trust for the public, and when the interests of the public are so directly involved as in these large irrigation projects, and when, further, there is no element of individual speculation or profit in the construction of the works, which are for the purpose of establishing the maximum number of homes on the land, it is the duty of every State to which the Reclamation Act is applicable to assist with every resource under its control.

It will be of interest to review several of the other provisions of the draft.

Units of measurement are established; the cubic foot per second for the flow of water and the acre-foot for volume. The miner's inch is fixed as one-fiftieth of a cubic foot per second, unless a different ratio has been agreed upon by contract or established by actual measurement or use. The miner's inch has been used in some States as a unit, but it is unsatisfactory, because it is not easily defined with exactness.

The amount of water which may be appropriated for irrigation is limited to 1 cubic foot per second for 70 acres or its equivalent.

While it is conceded that water used for irrigation must be appurtenant to the land, the fact should be recognized that conditions may arise to make it impracticable or uneconomical to continue to irrigate a particular tract. Provision is made so that the use of water may be severed from the land after application to the state engineer, due publication of notice of such intention, and approval by the state engineer. Similar provision is made for a change in the nature of the use to which the water is applied, or in the place of diversion, storage, or use.

The subject of seepage water is one that has given much trouble, and provision is made for the appropriation thereof in the same manner as other waters, with the requirement that the appropriator must pay reasonable charges for storage or carriage to the owners of the irrigation works from which it comes, provided that the seepage can be traced to such works beyond reasonable doubt.

All decisions of the state engineer or water commissioners affecting a substantial right are subject to appeal to the courts.

Adoption of code.

In the session of 1907 the Montana legislature considered a draft of a code prepared by a commission appointed by the governor which followed substantially the code referred to, but it was not adopted. The same is true with the legislature of Oregon.

During the year 1908 there has been a general movement toward the preparation of a code substantially in the form considered in the State of Oregon, and it is probable that it will be strongly urged upon the legislature early next year.

In many of the States statutes have been adopted tending toward the system discussed, and as this procedure is gradually enforced and modified as may be found advisable after experience, those States in which such laws have been enacted will do much toward the proper promotion of the irrigation industry.

It is generally conceded that those States in which statutes of this kind are not in force can best assist in the development of irrigation by following the principles and procedure there indicated.

One important feature of the law of irrigation has thus far received no attention in legislation, namely, the regulation of interstate waters. The decision of the United States Supreme Court in the Kansas-Colorado case (206 U. S., 46) and the decisions of some of the district courts of the United States in other cases, together with some decisions by state courts, have shown a tendency to consider this question, but in no case has there been an announcement of a principle which tends to meet the complicated conditions.

All the cases concerning interstate waters have involved only specific rights of the litigants; nothing has yet been accomplished outlining the method of providing for an adjudication of the waters of an interstate stream in such manner as to determine all the rights involved.

The principal difficulties arise from the fact that suit may be brought by one party against another and a decision obtained, which would not, however, bind anyone who is not party to the suit, and the complications in judicial procedure are such as to make it difficult, if not impracticable, under present conditions and rulings to bring into consideration in any one case all rights on interstate streams in two or more States and so arrange that one adjudication shall determine the rights of each party as against all other users of water from that stream.

Whether this matter can be adjusted by the courts themselves without the assistanc of legislation or whether legislation is absolutely necessary has not yet been demonstrated.

It has been proposed by some that Congress should provide for a tribunal empowered to investigate claims to the use of water of interstate streams and to prepare reports upon all facts affecting priorities and the use of water, the same to be submitted to the federal courts for adjudication, following in general the procedure outlined in the proposed code in regard to the adjustment of water rights within the State.

IRRIGATION.

By Dr. Samuel Fortier,

Chief of Irrigation Investigations, Office of Experiment Stations.

LAND NOW UNDER IRRIGATION IN THE UNITED STATES.

The following table gives estimates of the areas now irrigated in the arid States and Territories. For the States which have state engineers charged with the supervision of their water supplies, except Montana and Nevada, the estimates are made by the state engineers. Since these men are charged with the distribution of the waters of their respective States to the lands irrigated, their estimates are probably the best obtainable and very near the truth. For Arizona, Texas, Washington, and Nevada the estimates are made by men connected with the territorial and state agricultural colleges, whose duties have made them especially well-informed along this line. For California, Kansas, and Montana the estimates are made by representatives of the irrigation investigations of the United States Department of Agriculture, who have made studies of irrigation in those States, and can be considered the best authorities on conditions in them. The areas devoted to rice in Arkansas, Louisiana, and Texas are included in this table for convenience:

Areas irrigated in the United States.

State.	Area irrigated.	Authority.
	Acres.	
Arizona	200,000	R. H. Forbes, director Arizona Agricultural Experiment Station.
Arkansas (rice)	6,000	Yearbook, U. S. Department of Agriculture, 1907.
California	1,800,000	F. W. Roeding, U. S. Department of Agriculture.
Colorado	1,852,900	T. W. Jaycox, state engineer.
Idaho	2,665,000	Jas. Stephenson, state engineer.
Kansas	51,500	D. H. Bark, U. S. Department of Agriculture.
Louisiana (rice)	310,000	Yearbook, U. S. Department of Agriculture, 1907.
Montana	1,500,000	Samuel Fortier, U. S. Department of Agriculture.
Nebraska	250,000	
Nevada	500,000	G. H. True, University of Nevada.
New Mexico	400,000	V. L. Sullivan, territorial engineer.
North Dakota	[a] 64,300	T. R. Atkinson, state engineer.
Oregon	500,000	J. H. Lewis, state engineer.
South Dakota	42,000	S. H. Lea, state engineer.
Texas:		
General	500,000	J. C. Nagle, Texas Agricultural College.
Rice	284,000	Yearbook, U. S. Department of Agriculture, 1907.
Utah	830,000	W. W. McLaughlin, U. S. Department of Agriculture.
Washington	200,000	O. L. Waller, State College of Washington.
Wyoming	1,000,000	C. T. Johnston, state engineer.
	13,035,700	

---

[a] Includes total under Reclamation Service ditches, 44,800 acres, much of which is not yet irrigated.

In addition to the areas given in the table there is a constantly increasing area being irrigated in the humid States. This is especially true of the trucking districts of the South Atlantic and Gulf States. However, no reliable estimates of these areas can be made. Census Bulletin 16 gives the area in 1902 as 5,788 acres, which is an increase of 76 per cent over the area reported in 1899. Assuming a like rate of increase since that time would make the present area about 14,000 acres.

HOW MUCH MORE LAND CAN BE IRRIGATED.

Prior to 1890 erroneous ideas prevailed regarding the extent of land which could be irrigated in the arid region. So little was then known of the water resources of this region and so large seemed the irrigable lands that the most conservative estimates were much too large. Fifteen or more years ago the most generally accepted estimate was 100,000,000 acres. As data on the flow of western streams were accumulated by the United States Geological Survey and as more irrigation enterprises were carried out, men began to have a more accurate conception of the limitations of the water supply and the difficulties to be overcome in utilizing even a small portion of certain streams. From 100,000,000 acres the estimate shrunk to 90,000,000 and then to 75,000,000. For a number of years it halted at 65,000,000 acres, but from reports received from the best authority in each of the sixteen arid States and Territories during the months of September and October, 1908, the total extent of land possible of irrigation is below 45,000,000 acres. It is reasonable to conclude that this estimate is likewise too large.

Areas irrigable in arid region of the United States.

State.	Area irrigable.	Authority.
	Acres.	
Arizona	1,000,000	R. H. Forbes, Director Arizona Agricultural Experiment Station.
California	10,000,000	F. W. Roeding, U. S. Department of Agriculture.
Colorado	2,893,900	T. W. Jaycox, state engineer.
Idaho	5,446,000	James Stephenson, state engineer.
Kansas	103,500	D. H. Bark, U. S. Department of Agriculture.
Montana	6,000,000	Samuel Fortier, U. S. Department of Agriculture.
Nebraska	1,000,000	
Nevada	1,500,000	G. H. True, University of Nevada.
New Mexico	2,000,000	V. L. Sullivan, territorial engineer.
North Dakota	1,540,000	T. R. Atkinson, state engineer.
Oregon	3,000,000	J. H. Lewis, state engineer.
South Dakota	191,900	S. H. Lea, state engineer.
Texas:		
General	800,000	J. C. Nagle, Texas Agricultural College.
Utah	2,000,000	
Washington	1,000,000	O. L. Waller, State College of Washington.
Wyoming	6,200,000	C. T. Johnston, state engineer.
Total	44,375,300	

The spirit of the West is characterized by its hopefulness, and state engineers and others are more or less influenced by this. Besides, state officers desire, as a rule, to make a good showing for their respective commonwealths, and the tendency is to exaggerate rather than to minimize the extent of the natural resources. This is particularly true of those pertaining to land and water.

Such men are apt to base their conclusions on the total available supply. Quite frequently they fail to consider whether it would pay to utilize all this supply. There are limited portions of the arid region so favored by climatic and soil conditions that crops to the value of several hundred dollars per acre can be annually grown. In such localities a large amount of money may be profitably expended in providing a water supply by means of deep wells or storage reservoirs. In the vicinity of Riverside, Cal., the annual cost of water to irrigate citrus orchards exceeds on an average $22 per acre. This price includes the annual charge for maintenance and operation as well as the interest on the value of a water right. When the cost is so high, the water may be pumped to considerable heights, and storage reservoirs may be built whose first cost exceeds $100 per acre-foot. Wherever such costly undertakings are successful, practically all of the so-called available water supply can be utilized.

On the other hand, in the colder portions of the arid region, where the crops grown are confined chiefly to grains and grasses, water for irrigation has a low value, and the time will never come when any agency, individual, corporate, or governmental, can afford to build irrigation structures of such magnitude and cost as will serve to utilize all of the available water. Since this limitation, arising from the amount of money which can profitably be expended on any project, calls for the most careful consideration in perhaps 95 per cent of the entire region west of the Missouri River, it follows that the value of water in irrigation is a controlling factor in determining the extent of land which can be irrigated.

A large part of the total available water supply of the arid and semiarid regions of the United States is already used each crop-growing season. In taking water from natural streams and other sources of supply, conducting it frequently long distances, and applying it to arid lands much is wasted. When all losses are deducted, the quantity of water which subserves a useful purpose in the growth of plants is small in comparison to the quantity diverted. Those best informed quite generally believe that two-thirds of the water which is now diverted subserves no beneficial purpose in nourishing plant life. In the prevention of at least a part of this waste is to be found one of the best means of conserving the water supply of the arid region.

According to the census of 1900, the area irrigated in the United States in 1899 was 7,539,545 acres, while the special irrigation census of 1902 gave 9,487,077 acres. Assuming the same rate of increase the area irrigated in 1908 would be over 14,000,000 acres. This estimate, although doubtless too large, is confirmed in a way by recent reports from western state and territorial engineers. These aggregate for the sixteen Western States and Territories over 13,000,000 acres. Now, when one considers the quantity and value of the water which is annually applied to so large an extent of land and the high percentage which might readily be saved by a more economical use, the figures are startling. A saving of even 10 per cent of the quantity now used and making it available for other lands would provide a supply for 1,400,000 acres, representing a value of about $50,000,000. A consideration of the extent of the losses herein briefly outlined would seem to indicate that fully 33⅓ per cent of the present supply might be saved by the prevention of a part of the waste. The water thus saved would provide a supply for an additional acreage of four and one-third million acres, and represent a value of over $150,000,000.

Seepage and evaporation losses from canals by groups.

[In cubic feet per second.]

Number of canals tested.	Capacity.	Miles of canal tested.	Total discharge.	Total loss.	Percentage of loss per mile.
17	100 cubic feet per second or over	359.63	5,319.51	1,037.84	0.92
20	50 to 100 cubic feet per second	270.97	1,458.65	341.36	1.73
20	25 to 50 cubic feet per second	114.68	714.21	142.92	3.50
26	Less than 25 cubic feet per second	108.63	387.04	102.69	6.20

A commonly accepted estimate of the loss from ordinary unlined canals in earth is 25 per cent of the amount of water passing through the head gate, and from the results of measurements given this estimate seems to be conservative. The additional loss in the laterals and field ditch is usually as much more, so that as a rule, for every gallon of water that is taken from a stream only one-half reaches the fields to be irrigated. The portion which percolates through porous material is not always wasted. The seepage from one canal may be obtained by another at a lower elevation. On the other hand, seepage waters frequently do no end of damage to low-lying lands and the benefit gained by a second diversion and use is more than offset by the damage done in water-logging soils.

LOSSES ARISING FROM IMPERFECT WATER-RIGHT CONTRACTS.

In the large majority of canal contracts, the canal company agrees to supply a stream of a given size continuously or in rotation for the irrigation of a definite tract of land. In the event of a shortage of water each water-right holder receives only his pro rata share of the water available. Since each water user is expressly forbidden by the terms of the contract to use the water thus purchased on any land other than that specified, there is no inducement for him to economize by using less than the amount stated in the contract.

This form of contract was popular at a time when water was cheap and abundant, and in consequence the water allotted to each acre is usually far in excess of the actual requirements of the crops when the subsoil becomes partially filled with waste water.

In some of the more recently organized irrigation companies the water is measured out to each user and he pays only for what he gets. Such contracts place no limitations on the place of use. In the most common form of contract the self-interest of the irrigator leads him to waste water by applying too much; in the later form his interests are best served by the strictest economy. If in future all companies organized for this object could be induced to sell water by measurement, requiring the user to pay a quantity rather than an acreage rate, much water could be saved. Most farmers who now use and waste every summer sufficient water to cover their fields to a depth of 4 feet under the old system would find that they could produce more valuable crops with the use of 2 feet under the form of contract herein recommended.

LOSSES DUE TO UNJUST AND IRREGULAR DISTRIBUTION.

The large majority of rights to the use of water has never been determined by a competent tribunal. In consequence, disputes among neighbors over the quantities each is entitled to are common. Such uncertainty leads to overreaching and injustice. When one man takes twice as much water as properly belongs to him his neighbor may have none. To insure a supply it is usually necessary for one man to stand guard over the headgate while his comrade tends to the irrigation of the field. Under such conditions it is impossible to use water to the best advantage and in the most economical way.

LOSSES FROM POORLY PREPARED FIELDS.

The surface of the fields is rarely prepared with that skill and care which rapid and effective watering demands. A thorough grading and smoothing of the surface is necessary before water can be evenly distributed over the surface. Failure to prepare the surface properly results most frequently from carelessness, because money and labor thus spent bring in large returns. In addition to the amount of water saved, the labor of irrigating the properly prepared field is lessened, the soil is not damaged by an overdose of water in the low places, there is considerable increase in the yield, and the quality of the crop is improved.

LOSSES IN THE APPLICATION OF WATER.

These losses are due to carelessness and unskillful use, evaporation from the wet soil, and percolation beyond the reach of the roots of plants. All of these losses are increased when the surface is not properly graded, but even in well-graded fields it is possible to lose a large part of the water which is delivered at the highest point by unskillful use. The application of frequent light irrigations on the surface tends to keep the surface moist the greater part of the time, and in consequence much of the moisture is evaporated. In the best methods of applying the water the losses due to evaporation will be considerable unless frequent cultivation is resorted to. Deep percolation is another source of loss. When the subsoil is porous it is difficult to prevent, even under the best practice, considerable quantities from percolating to depths far beyond the deepest roots. On the other hand, in stiff retentive soils there is not sufficient percolation, and under careless use a large part is allowed to flow off the surface and pass beyond the tract to be watered.

THE RELATION OF IRRIGATION TO FORESTS.

In Bulletin No. 38 of the Utah Agricultural Experiment Station, the beneficial effects of forests in increasing the water supply is set forth in the following words:

> The municipal engineer increases the size of sewers which drain areas covered with an impervious lining, such as the roofs of buildings, paved streets, and cemented sidewalks. He well knows that if a heavy rain falls on such a district, the greater part will immediately run off and the sewer must be made large enough to carry this flow. The same amount of rain may fall on lawns, vacant lots, or porous streets without producing more than 40 or 50 per cent of the maximum discharge.

> In like manner, when rain falls on a mountain slope that has been denuded of its natural forest growth, there is little, if any, vegetable mold to absorb and retain, for a while, the moisture. The rain drops fall on the rocky surface, gather into rills, and these into streams, until a mountain torrent is formed. These intermittent streams that flow with great rapidity are in nearly every sense detrimental to the irrigator.
>
> On well-wooded mountain slopes the case is different. Here the leaf mold of centuries absorbs and holds back the rainfall, and weeks or even months afterwards some field or orchard far down in the valley may be invigorated by its presence. Here, too, the winter snow finds a resting place, sheltered alike from wind and sunshine. The heat of spring melts the snow gradually and permits a large part to sink into the vegetable mold, from which it is gradually conveyed beneath the surface to do good service to the irrigators of the plains.

In the foregoing brief paragraphs are set forth the chief benefits of forests in equalizing the streams. It is not true, as some contend, that forests increase the water supply. The vegetable matter which covers forests not only retains a large part of the natural precipitation but also no small portion of the melting snows in seasons of the year when water is abundant and possesses little or no value. The water which is thus held back in these natural storage reservoirs usually seeps, in course of time, down the mountain slopes and forms the chief source of late summer and autumn stream flow. Vegetable mold also prevents the loss of water by evaporation from the surface. Many experiments have been made to determine the effect of such mulches in preventing evaporation, and almost without exception all go to show the beneficial effects of such a mulch.

The part which forests play in equalizing the water supply, holding back a portion of the spring floods and delivering the greater part of the water thus stored later on in the season to feed the springs at a lower elevation, is well understood and has been fully presented of late in a large number of publications relating to forestry and irrigation.

There are, however, other phases of the subject which should not in fairness be overlooked. One of these is the effect of deep, compact snowdrifts which lodge in ravines and melt slowly during the summer months. There is no question that most of the water supply which is derived from this source is usually accredited to the beneficial effects of forest growth. Any one who is familiar with the main ranges of the Rocky Mountain region has noticed large accumulations of compact snow in the deep ravines of the mountains during the summer and autumn months when all the snow has disappeared from the forests. Men who have closely observed the effects of these snowdrifts are led to believe they conserve more water than the forests.

There is another phase of this subject which deserves a passing word. That is the large amount of water required to nourish forest trees. It is well known that every plant, whether it be a stalk of grain or an orchard tree, requires a large amount of water to maintain a healthy growth. The same is true of forest trees, with this difference, that as their transpiration surface is much greater, much more water is required. When this water is withdrawn from the soil in seasons of scarcity it must tend to greatly reduce the quantity of water which reaches the streams in the immediate neighborhood.

THE RELATION OF IRRIGATION TO FLOODS.

The quantity of water diverted from streams in flood time for the irrigation of land is usually so small in comparison to the stream itself as to produce little or no effect in lessening the flow or in preventing destructive action by floods. While this has been generally recognized, the building of storage reservoirs for such purposes has been quite generally and persistently advocated for a number of years. Many prominent men outside of the engineering profession and quite a number of hydraulic engineers have advocated this means of controlling flood waters. They claim that if the water of streams and their tributaries which are subject to destructive floods were diverted into mountain reservoirs, the withdrawal of so much water would greatly lessen, if not altogether prevent, the floods. In advocating a plan of this character they have failed to outline any practical way in which it can be done. It is not likely that storage reservoirs will ever be built for the sole purpose of preventing floods. The cost will be prohibitive. This may be illustrated by reference to the Sacramento River in California. This river is quite small in comparison with others subject to floods, but to have provided storage for the discharge of this stream below the mouth of Feather River for twenty-four hours on March 19, 1907, would have cost at least $20,000,000. When one remembers that this flood lasted for four days with extremely high water, both before and after this period, the magnitude of the undertaking is apparent. Furthermore, the rapid filling up of such reservoirs with silt borne by flood waters would gradually reduce their capacity. In nearly every case experienced hydraulic engineers are of the opinion that for purposes of river control it would be much more economical to provide a passageway for flood water by means of levees and channel excavations than to attempt to hold the water behind costly dams at the higher elevations.

If it is intended to build storage reservoirs to provide water supplies for the irrigation of lands and at the same time utilize them as occasion arises for the prevention of floods, the plan is not feasible. There would be diverse interests that could not be brought together. The landowners in the more elevated portions of a drainage basin would want storage reservoirs solely for irrigation purposes. Those in the lower portions of the basin would want them most for protection against overflow. One and the same reservoir could not well serve both purposes. The irrigator would never consent to take chances on a half-filled reservoir for the sake of keeping it empty to provide for a flood which might never come.

IRRIGATION LAWS AND ORGANIZATIONS.

By R. P. Teele,
Office of Experimental Stations.

WHAT AGENCIES ARE DEVELOPING IRRIGATION.

INDIVIDUAL.

The early irrigation works were built almost entirely by individuals or groups of individuals working together, who built small works, taking water from streams for the watering of their own lands. This type of development is past in most arid sections, because the opportunities for it are fully utilized, but in the semiarid region it is probable that large areas will still be watered in this way, as the advantages of irrigation in sections where crops can be grown without it are realized. Irrigation by individuals, however, has still a very large field where water is pumped from wells or stored in small reservoirs, which are filled from the torrential flow of streams or with rainwater collected from adjacent lands.

Most large ditches cover more lands than can be irrigated by them, but they raise the level of the ground water to such an extent that it can be pumped to the surface within the limits of allowable cost. A great many such pumping plants have been, and are being, installed by individuals, and there is great opportunity for extension along this line. The pumping of water from the soil in this way produces a double use of water, for the source of supply is water already used for irrigation. While in some sections of southern California and southern Texas large areas are irrigated with water pumped from underground sources, it is generally true that this source is just beginning to be utilized. This field is peculiarly adapted to development by individuals because of the many advantages of pumping water at the point of use, the greatest of which are the saving of the expense of building conduits to carry the water to the place of use and the avoidance of all losses of water in transit, which losses are very large if water is carried in earthen ditches, and which can be prevented only at heavy expense. It is true that small pumping plants are not so efficient as larger ones, and this is especially true of engines of all types. However, the long-distance transmission of electric power makes it possible to develop power in large central stations where conditions are especially favorable and distribute it to individual or neighborhood pumping plants. In this way the cost of power is reduced to a minimum, as the electric motors and pumps used by the farmers require almost no attendance, leaving the farmer free to attend to his other duties.

The storage of storm water in small reservoirs is another field of great possibilities which belongs naturally to the individual and which has been barely touched as yet. The opportunities for such development are greatest on the plains where stock raising must always be the principal industry. In the past, great areas have been unused because flocks and herds must be kept within the reach of water. The storing of the storm water makes it possible to use great areas formerly unavailable, and it also enables the stockman to raise forage for feeding during winter storms, thus preventing the losses due to starvation when winter feed is not supplied, which losses often reach 10 per cent in a single storm. The greater part of the plains area is beyond the reach of water from streams, and underground water is at such great depths that the cost of pumping it to the surface is prohibitive, but these plains have innumerable ravines and depressions in which storm water can be stored at small expense.

The small precipitation of the plains for the most part comes in heavy showers which run off quickly, causing floods in the usually dry drainage channels, which do great damage. If this water can be held back in reservoirs they will serve the triple purpose of providing stock water, irrigation water, and checking floods. This work has been begun and has proven its value, as shown by instances cited in a report on this subject published by the U. S. Department of Agriculture.[a] No other one thing promises so great returns from the Great Plains lying to the east of the Rocky Mountains.

Since storage dams are always a menace to land lying below them, the construction of such dams should be under the supervision of competent local officials who should be empowered to prescribe rules for their construction, to inspect them during and after construction, and to order necessary changes and repairs. The National Government is aiding in this work through the United States Department of Agriculture, which has published bulletins showing the possibilities of such storage, the returns secured, and the methods of construction which should be adopted to insure the permanency of dams and protect the land below them from damage. Any law enacted by the General Government providing for the leasing of grazing areas should provide in some way for the encouragement of the building of storage reservoirs and should permit the cultivation of a small part of each leasehold.

CORPORATE.

Following the individual and partnership ditches, which watered a single farm or a few neighboring farms along the rivers, came the large ditches built by corporations to water the higher lands of the river valleys of the arid region. These corporations have built most of the large ditches now in use. The great increase in the value of desert lands, when water was supplied for their irrigation, attracted large amounts of capital into this field in the years immediately preceding and following 1880.

The prevailing type of corporation was a company which built the irrigation works and sold water rights to settlers, the expectation being that the sale of water rights would repay the cost of construction with a good profit, and leave the company still in possession of the works and franchises, the contracts with the water users providing for the payment of annual charges to cover the cost of maintenance and operation. The promoters thus expected to secure the return of their entire investment, retain the property, and make it pay interest on its cost. Almost without exception these companies have been financial failures, but agricultural successes. The lands were settled slowly, so that water rights were not sold; maintenance charges were based on the entire acreage to be irrigated, and the payment from the small areas watered did not begin to cover the cost of maintenance and interest charges. Meanwhile the farmers prospered, and eventually the lands were settled but not until interest and upkeep had brought financial ruin to the companies building the works.

---

[a] O. E. S. Bul. 179—Small Reservoirs in Wyoming, Montana, and South Dakota, by F. C. Herrmann.

A modification of this plan which became very popular was a provision that when all or a large percentage of the water rights represented by a canal were sold the works were to become the property of the water-right holders, to be maintained and operated by them. The water-right contracts were to be exchanged for stock in a new company which should take over the works and operate them. This has not proven much more successful, from the standpoint of the original investor, but it has resulted in making this the prevailing type of canal company throughout the arid region. By far the larger part of the existing irrigation works in the arid region is owned and controlled by stock companies, the stock of which is in the hands of the water users. The laws of all the States accepting the conditions of the Carey Act, and the reclamation law, providing for the construction of irrigation works by the General Government, provide that the works built shall be turned over to companies of this type. In general, then, this may be said to be the standard type of irrigation corporation. There are some companies which supply water to customers without the sale of water rights, securing their entire returns from the annual charges. These are most common in the rice districts of Louisiana and Texas, although they exist in other places.

In all of the arid States canal companies are given the right of eminent domain, and the States have the right to regulate charges, usually through the county commissioners.

There is still considerable construction being carried on by canal companies of the types just described, but the greater part of present construction is done by quasi-public corporations under state control, or by the National Government under the reclamation law.

STATE.

In two instances States have undertaken directly the construction of irrigation works, but in both instances the undertakings have been abandoned. Colorado sought to utilize its convict labor in the building of ditches, but abandoned the attempt before completing any works. Montana attempted to build its own ditches under the Carey Act, but here, too, direct state construction was abandoned before any projects were completed.

The arid States do, however, aid in the development of irrigation under two classes of laws: Irrigation district laws, and laws accepting the conditions of the Carey Act.

IRRIGATION DISTRICTS.

Irrigation districts are given the power, when properly organized, to issue bonds to secure funds for the purchase and construction of irrigation works; to levy and collect taxes for the maintenance and operation of these works, for the payment of interest, and for the creation of sinking funds to pay off the bonds issued. They are organized under public supervision, and provision is made for the establishment of the validity of their organization. The bonds and the taxes levied are liens upon the lands of the districts in the same manner as are county and state taxes. Usually county treasurers are ex-officio treasurers of irrigation districts within their respective counties.

The irrigation district laws of the several States are similar in a general way, but differ much in detail. They provide that the lands susceptible of irrigation from a common source and by the same system of irrigation works may be organized into an irrigation district. Usually the organization of an irrigation district is to be initiated by petitioning the county commissioners of the county in which a majority of the lands are situated. When the plans have been formulated and the proposed boundaries have been fixed an election is held to decide upon the organization of the district. The qualifications of electors differ, the Colorado law being as follows:

> All persons shall be entitled to vote who are resident freeholders of agricultural lands within said district, or who are owners of lands to the extent of 40 acres or more within said district and reside within any county into which any part of said district shall extend, and who are qualified electors under the general election laws of the State, and who shall have paid property taxes on property located within the district during the year preceding any such election. (Laws of 1907, p. 488.)

The majority required to carry such an election also varies in the different States. In Colorado a majority vote only is required for either the organization of a district or the issue of bonds. In Idaho a two-thirds vote is required for either purpose.

The manner of assessing the cost upon the lands also varies. In Colorado it is a flat rate per acre; while in Idaho the cost is apportioned in proportion to the benefits received, while the cost of maintenance and operation may be provided for by tolls or by assessments on the lands, or by a combination of the two.

The bonds run twenty years. Only the interest is payable during the first ten years. At the end of the eleventh year 5 per cent of the bonds mature; at the end of the twelfth year, 6 per cent; at the end of the thirteenth year, 7 per cent; fourteenth year, 8 per cent; fifteenth year, 9 per cent; sixteenth year, 10 per cent; seventeenth year, 11 per cent; eighteenth year, 13 per cent; nineteenth year, 15 per cent; and twentieth year, 16 per cent.

Irrigation-district laws have been used principally for the purchase of works already built and for their enlargement or extension. They are not adapted to the construction of new works in the arid region because a large part of the lands to be reclaimed belongs either to the General Government or the States and can not be taxed for irrigation-district purposes, and consequently can not become security for the bonds of districts. To obviate this objection as far as possible Idaho provided by law that state lands included within irrigation districts should be liable for district taxes, and that the taxes paid by the State should be added to the price of these lands when sold by the State. Idaho provided also for the purchase of irrigation-district bonds by the General Government under the Reclamation Act. However, neither of these provisions has had opportunity to demonstrate its utility.

They suggest, however, the possibility of adapting these laws to the development of new lands and point out an existing weakness in other forms of organization. The building of a canal from which a tract of land can be supplied with water greatly increases the value of the land. Under the usual forms of canal organization the owner of land under a canal may or may not purchase water rights, but the value of his property is greatly enhanced by the mere possibility of securing water. Yet there is no way in which he can be made to contribute to the cost of the irrigation works. This condition was one of the primary reasons for the passage of irrigation-district laws. Under them all private lands susceptible of irrigation from the work built must contribute to the cost. The taxes levied by the district can not be met from unimproved lands, and improvement of all lands covered is therefore forced. Lands owned by the State or General Government can not, however, be made to contribute. It seems that both the States and the nation should provide for the payment of district taxes on their lands, with proper provision, of course, for approval of plans by public officials, for the addition of taxes paid to the price of the public land, and limitations upon the percentage of public land in the total area of a district.

District laws have a further advantage in that payments on the bonds for the first ten years are limited to the interest, whereas other laws require that payments on the principal begin at once. Often the preparing of land for irrigation costs as much as the irrigation works and is a heavy burden on the settler during the first year of his settlement. Under district laws he is free to meet these expenses and pay the cost of his irrigation works when he has become established.

District laws place the control of irrigation works in the hands of officials elected by the owners of the lands watered, the difference between this control and that of the stock companies previously described being that in the district all landowners have equal voice in the control of the works, while in the stock company the stock and the influence of its holder are usually in proportion to the acreage watered.

THE CAREY ACT.

Under what is known as the "Carey Act" (an act making appropriations for sundry civil expenses of the Government for the fiscal year ending June 30, 1895, and for other purposes, 28 Stat., 372–422) large areas have been developed under a sort of cooperation between the nation, the State, corporations, and individuals. The General Government gives the lands to the States on condition of their reclamation; the States enter into contracts with corporations to reclaim these lands, and sell the lands to individuals.

Section 4 of the act above mentioned, which constitutes the so-called "Carey Act," provides for the granting to each of the arid

States free of cost for survey or price such areas of desert land, not to exceed 1,000,000 acres, "as the State may cause to be irrigated, reclaimed, occupied, and not less than 20 acres of each 160 acres irrigated by actual settlers," within ten years from the passage of the act.

In 1896 Congress passed an act providing that a lien might be placed on these lands to secure the payment of the cost of the irrigation works built to reclaim them, and in 1901 the time limit contained in the original act was removed, the law providing that the ten years within which lands must be reclaimed "shall begin to run from the date of approval by the Secretary of the Interior of the States' application for the segregation of such lands," and giving the Secretary of the Interior authority, in his discretion, to extend this time for an additional five years.

Further modification in 1908 granted to each of the States of Wyoming and Idaho, which had applied for most of the original 1,000,000 acres allotted to them, an additional 1,000,000 acres.

The conditions of this act have been accepted by the following States: Colorado, Idaho, Montana, Nevada, Oregon, Utah, Washington, and Wyoming.

The plans adopted by the States for carrying out the reclamation of these lands vary in details, but are similar in their general outlines. The system adopted by the State of Wyoming is described by the state engineer as follows:

> The company proposing to carry on such development first makes its surveys and plans for this work; then secures the necessary permits from the state engineer's office; then makes its request and proposal to the state board of land commissioners, composed of the governor, the secretary of state, and the superintendent of public instruction. This request and proposal describe the lands that are to be irrigated and contain the proposition of the company to the State as to price of water rights and a permanent interest in irrigation works, the form of contract to be used, and other particulars. If the state board of land commissioners approves the proposition, maps and a request for the segregation of the lands are transmitted to the proper local land office. The lands designated are immediately withdrawn from entry, and the local land office submits the request to the General Land Office at Washington, where the approval of the Secretary of the Interior finally places the State in control of the land. The works are then completed by the company. The land can not be taken up until the settler shows the State that he has entered into contract with the company for a sufficient water right for his lands and a perpetual interest in the irrigation works, proportioned in the ratio of the area of his land to the entire tract to be reclaimed. When the irrigation works are completed, the state engineer makes an inspection, and if they are found to comply with the plans and specifications which have been already passed upon by him, the state board of land commissioners is so notified; whereupon the board makes a request to the Government that patent issue. The patent comes to the State, and the lands are sold and patent given the settler upon the payment of 50 cents per acre, the payments for water rights being made to the company building the works.

The areas segregated and the areas patented to the States under the Carey Act up to July 1, 1908, as shown by the report of the Commissioner of the General Land Office, are as follows:

Segregations applied for under the act of August 18, 1894 (28 Stat. L., 372–422), and the acts amendatory thereof, with the action taken thereon, from the passage of the act to July 1, 1908.

[Areas in acres.]

State.	Selected.	Rejected, relinquished, etc.	Approved, not patented.	Approved and patented.
Colorado	59,807.94	5,704.95	54,102.99	....
Idaho	1,180,566.17	265,828.94	662,254.00	186,954.90
Montana	104,587.98	2,792.53	83,498.54	18,296.91
Nevada	12,644.61	8,000.00	....	....
Oregon	432,202.53	78,507.31	245,287.52	50,063.13
Utah	328,327.40	236,980.83	48,226.74	....
Washington	155,649.20	155,649.20	....	....
Wyoming	965,568.64	196,994.18	623,054.44	7,768.72
Total	3,239,284.66	952,458.13	1,716,424.23	263,083.66

Oregon segregation list No. 5, covering 58,344.57 acres, is pending before the Secretary on appeal from the decision of this office rejecting it.

Wyoming segregation list No. 27, covering 26,936.03 acres, was rejected by this office, which decision was affirmed by the department, but said decision has not yet become final.

As before stated, Congress in 1908 granted to Wyoming and Idaho, the only States which had applied for nearly the entire original allotment, additional areas of 1,000,000 acres each, indicating an intention to extend the area indefinitely as there is a demand for it. This seems to be a wise attitude.

The object of all our land laws has been to get the public lands into the hands of those who will make homes on them, rather than to secure a revenue from them. The Carey Act has proved well adapted to that end, and so long as it does this there seems to be no reason why there should be any limit on the area which may be selected by each State under this law.

The laws of all the States provide that when the water rights are sold and paid for the works shall become the property of the water-right holders and shall be turned over to a company composed of these parties to be maintained and operated by them, the provisions in this regard being similar to those of the reclamation law.

NATIONAL.

(Discussion of reclamation law omitted on account of its being under another department.)

DO PRESENT LAWS TEND TO PROMOTE IRRIGATION FULLY AND WISELY?

The object of all our laws relating to irrigation is to secure the establishment of the largest possible number of permanent prosperous homes on the lands of the arid region. All these laws must be judged by this standard. The establishment of homes in the arid region requires the cooperation of three parties—capitalists, farmers, and the public—and the interest of each must be guarded in any successful system of irrigation law. The capitalist must be given reasonable security for the return of his investment; the farmer must have a reasonable guaranty of a water supply and must be protected from exploitation by the capitalist; and the public must be assured that its resources will be economically used.

SECURITY FOR CAPITAL INVESTED.

As pointed out in the discussion of agencies now developing irrigation, the day of enterprises carried out by the individual is past. The construction of the large irrigation works necessary to store and divert the water of the large streams of the arid region requires the investment of large amounts of capital, and in order that this may be put into these enterprises it must have at least as great a degree of security as exists in other lines of investment. This security depends upon both the farmers and the public. The builders of irrigation works must be given a lien upon the property values created by these works sufficient to guarantee a return upon their investment, and in order that these property values may be stable and therefore good security, the water supply on which these values rest must be guaranteed within reasonable limits.

The three agencies under which the largest development is now taking place are: Irrigation districts, the Carey Act companies, and the United States Reclamation Service. Under the irrigation-district laws capital is secured by the sale of bonds, which are a lien upon the lands of the districts, and under the Carey Act the companies building the works sell water rights, the deferred payments on which become liens upon the lands. Under the reclamation law the Government secures itself by taking liens upon the lands. It seems, then, that under these laws capital is amply secured so far as the farmer is concerned, and the large amounts of capital being put into irrigation works under all these laws indicate that the security is considered sufficient.

This security is almost valueless, however, unless the water supply is reasonably sure, since the lands of the arid region are rendered valuable only by the use of water. This has been recognized from the earliest settlement of the arid region, and the legislatures and courts of the arid States and of the General Government have been trying from that time to this, to develop a system of laws which will render rights to water as secure as those to other forms of property. In order that this property may be as secure as other property, two things are essential: That all rights be defined, and that some effective system of protection be provided. There are in the arid region two systems of water law, one of which fulfills these requirements, and the other of which renders any such security impossible.

Certain States have recognized the common-law doctrine of riparian rights, which, in the very nature of the doctrine precludes any defining of rights. The riparian owner is held to have the right to a reasonable use of the water of the stream to which his land is riparian, which use must not interfere with a like use by all other riparian owners. What is a reasonable use at one time may not be at another time, and any riparian owner may at any time enlarge or change his use of the water, every change making necessary a new adjustment of use by all other owners. As a result, there can be no security of rights where riparian rights are recognized, except through monopoly created by the uniting of ownership in a single party. Some of these States have enacted laws providing for the condemnation of riparian rights, and this seems to be the only equitable way in which the handicap created by the recognition of riparian rights can be overcome.

Most of the arid States have either abrogated the doctrine of riparian rights or their courts have held that it never existed within their territories because of its inapplicability to arid conditions. These States allow the diversion of water from their streams for the irrigation of any lands, whether riparian or not. They have adopted the principle that "the first in time is the first in right," which in practice means that the one first using water from a given source has a right to continue that use to the extent of the original use, as against anyone taking water from the same source at a later date, and that when there is not water enough to supply all demands the latest user is first deprived of a supply, and so on, in order as the supply decreases. The carrying out of this system requires that all rights be defined as to both time and extent, and an administrative system to divide the water among those entitled to its use, according to their respective rights. These States have provided for the defining of rights either by the courts in a special procedure, or by administrative boards, with appeal to the courts. They have provided for either the granting of rights by the State or for the securing of rights by appropriation, which are later defined by the courts; and they have provided for the distribution of water in accordance with these decrees by state officials. This system gives the necessary security to water rights. The records of the state officials show what rights are already in existence; they show whether the stream flow is sufficient to satisfy existing demand, and whether there is more water to be secured by the builders of new ditches or reservoirs; and state officials distribute the water. There have been, of course, many crudities in court decrees, and injustice has been done in some cases, but the system is good, and should be maintained. One serious weakness has developed in this system. The courses of many of our large streams lie in more than one State, and the administrative system of a State can not extend beyond its boundaries. This weakness has been met so far by appeal to the United States courts. There has been strong demand for some administrative provision for the distribution of water from interstate streams, but no such provision has been made so far. The United States courts have uniformly upheld the doctrine of priority, regardless of state lines, and have protected the users in the lower States against later users in the upper States. A physical examination of our interstate streams leads to the conclusion that there is not likely to be serious conflict between the States on these streams. In most cases the physical conditions are such that users in the upper States can not do serious permanent injury to the users in the lower States.

In general, therefore, from the standpoint of the capitalist, the existing water laws of the arid States, except those which have recognized riparian rights, give the necessary protection to water rights.

PROTECTION FOR THE FARMER.

As regards the water supply, the canal company stands in the same relation to the farmer that the State does to the canal company. There has not been, however, the same provision for the protection of the rights of the farmer. Many canal companies have agreed to supply water to far more land than their canals will serve properly, and have inserted in their agreements provision that whatever water their canals receive shall be prorated among all holders of water rights, and that they are not responsible for any shortage due to causes beyond their control or to shortage in the source of supply. A common provision in such agreements is that the company will not sell rights to more than the "estimated capacity" of its ditch, but this is little protection, because there is no limit put on the "estimate" of the ditch owner. While such provisions have worked many hardships on the farmers they have tended to an economical use of water, because farmers under canals supplying insufficient water have been compelled to practice a degree of economy which they might never have attained except under necessity. There should be legislation by the States making canal companies responsible for shortages due to overselling, because the new settler, coming into an arid region is in no position to determine for himself whether the company selling him a water right is in a position to furnish him a full supply.

As pointed out in the discussion of agencies developing irrigation, the prevailing type of ditch company is one in which the works ultimately become the property of the water users, and that irrigation-district laws, the Carey Act, and the reclamation law all provide for the control of the works by the water users. None of these laws protects him, however, from purchasing an interest in a canal which will not supply him with sufficient water. He guarantees his payments for these works with a lien upon his lands, but has no recourse if he is not supplied enough water to enable him to raise crops with which to meet his payments.

THE GUARANTY OF ECONOMICAL USE.

Throughout the arid region, except in the States which recognize riparian rights, the extent of a right to water is the quantity which has been put to a beneficial use, and the right ceases to exist when the use is abandoned. In some States the period of nonuse which constitutes abandonment is fixed by law, while in others this is left to the courts. These laws, if properly enforced, effectively prevent the holding of rights unused for speculation, as land is so often held.

These States have also laws prohibiting the waste of water, and as a rule the officials charged with distributing water are required to prevent waste, but in practice this is extremely difficult, since the officials can not patrol the ditches, but must turn out to each canal the water which its owners demand within the limit of their rights. These laws do, however, usually prevent absolute waste. But between positive waste and the most economical use there is a very wide margin for saving, which can be realized only by making it to the interest of the water user to be economical.

Considered from the standpoint of their influence on the economical use of water, the laws of the arid States fall in two classes—those which allow the acquirement of rights to fixed quantities of water and those which allow the acquirement of rights to water sufficient for fixed areas of land. It has been found that the granting of rights to fixed volumes of water with the privilege of using this water on as much or as little land as desired brings about the most economical use of water. Having a certain volume of water, it is to the interest of the owner to secure as large a return as possible from this supply. On the other hand, the water user who is entitled to sufficient water for a certain area has no incentive to economy. His saving brings him nothing, but goes to some one else. Under these circumstances he can not be expected to spend time or money in saving water, as he would do if his efforts enabled him to water more land and thereby increase his returns.

The fear of the accumulation of rights in the hands of nonusers or "water lords," and of their exploitation of the water users has led to the enactment of laws attaching rights to particular tracts of land, to the prohibition of the ownership of water rights apart from the land on which the water is to be used, and to the limiting of rights to the needs of these areas. But in practice it has not proven satisfactory. It has been found necessary to provide for the transfer of rights from the areas in connection with which they were acquired to other lands, the needs of which may or may not be the same as the needs of the areas from which the rights are transferred, thus rendering all rights uncertain as to quantity, and encouraging the liberal use of water in order to be sure and always have enough. It has been shown in the preceding discussion that there has been no tendency to "water lordism," but that the prevailing type of canal organization is the stock company composed of the water users, while all the laws under which development is now taking place provide for placing the ultimate ownership and control of irrigation works in the hands of the owner of the lands served. It is believed, therefore, that the reasons which brought into existence the laws attaching rights to definite areas of land and measuring them by the necessities of these lands have ceased to exist if they ever did exist. It is believed that the only system which can be expected to lead to the economical use of water is the limiting of rights to definite quantities of water, leaving the water-right holder to use this on as much or as little land as he will.

UPON WHAT MODIFICATIONS OF LAW WILL THE BEST PERMANENT DEVELOPMENT OF IRRIGATION SYSTEMS DEPEND?

Modifications of existing laws have been suggested in the preceding discussion. These suggestions lead to the following definite recommendations:

FEDERAL LAWS.

Limited areas of public lands within the area of irrigation districts should be made liable for irrigation-district taxes, the taxes thus paid to be added to the selling price of the lands.

The provisions of the Carey Act should be extended to the Territories, and the limit of the area which may be selected by each State should be removed.

The reclamation law should be amended by providing for extensions of time for payments on water rights whenever a full supply of water is not available, and for release of mortgages in case the shortage is permanent.

STATE LAWS.

The law of riparian rights, so far as it is recognized in the arid region, should be abrogated, allowing the use of water on all lands, whether they border on streams or not. In this, vested rights should not be injured, but should be condemned for the public good. A permanent settlement of rights seems to be impossible until this is done.

Those States which have not already done so should provide for the defining of existing rights to water, for the orderly acquirement of rights in the future, and for the division of the water of streams among those entitled to its use by public officials.

Laws should be enacted prescribing severe penalties for selling rights to more water than can be supplied, since settlers have no means of ascertaining the ability of a canal company to fulfill its contracts.

All rights to water should be based on quantities rather than areas, since only in that way can economical use be secured.

State lands within the limits of irrigation districts should be made liable for district taxes, with proper limitations as to the proportion of the whole area which may be state lands, and for approval of district plans by state officials; the taxes paid being added to the price of the lands when sold.

UNDERGROUND WATERS.

By W. C. Mendenhall,
Water Resources Branch, United States Geological Survey.

Underground waters constitute one of the three natural subdivisions of precipitation. These subdivisions are evaporation, surface run-off, and percolation. That part of the precipitation which passes below the soil surface by seepage into the soil pores becomes thereby a part of the body of underground waters. Eventually it is returned to the air to begin again its circuit through the air and back to earth. This return to the air may be accomplished very quickly or very slowly. Capillarity and evaporation may withdraw the earth moisture and return it to the atmosphere before it has reached any considerable depth in the soil mantle, or it may pass beyond the reach of these forces and begin a journey through the soil pores or the rock masses that may continue for a few hundred feet or a few hundred miles. The waters may even accumulate in a porous rock mass and may remain there stored and practically motionless for centuries or for geologic epochs. All of that portion of the precipitation that is absorbed and remains underground for either a long or a short period, following a long or a short course, constitutes the ground water. There is, in addition, a certain amount of original water, either magmatic or included with the sediments at the time of their deposition. The aggregate quantity of this is undoubtedly very great, but as it is in general inaccessible to man, little attention need be given it in a discussion of water as a resource.

An estimate of the quantity of surface waters is a large but a relatively simple problem. It can be solved by the patient application through long periods of well-determined engineering methods. The resulting estimates, since they are those of the engineer and the mathematician, are correct within a limited percentage of error, because all the factors of the problem are capable of close determination. But although the quantity of surface waters is measurable, its maximum possible use is not rigidly determinable, because that problem contains a number of variable factors. Man's mastery over the mechanic arts is constantly increasing. That which is impossible to him to-day becomes possible to-morrow. Furthermore, economic controls are constantly shifting. A water power that is not available this year, not because of unsolved mechanical problems, but because of cost, may be easily available next year, because a railroad has been built, or a mine has been opened, or population has shifted. These are things that neither the mathematician nor the economist can predict. They introduce into the problem of determining the possible future use of any resource a factor so variable that the result is of doubtful value. Suggestions only can be made; rigid determinations are not possible.

As to ground waters, neither the determination of the total quantity nor of the maximum use is capable of close solution. The first involves general estimates of factors not directly measurable, such as the percentage of pore space in deeply buried and inaccessible material, soils, and rocks. These estimates must be made by the deductions of an inexact science, geology, instead of through the measurements of an exact science, engineering. The same variables enter into the determination of the maximum possible use of ground waters as into the maximum possible use of surface waters, namely, different and constantly shifting economic controls. It may be highly profitable to pump ground waters 500 feet vertically for the irrigation of citrus lands in southern California whose product is worth $250 per acre per year, whereas it may not be possible to pump 50 feet vertically in another locality, where the products are not worth $10 per acre per year. Notwithstanding, some such crude estimate as may be made of the quantity of these resources is helpful, since it gives us a concrete conception of the amounts with which we are dealing.

QUANTITY.

Estimates that vary widely have been made as to the total amount of this ground water. These estimates range from an amount sufficient to cover the earth to a depth of 96 feet (Fuller) to an amount sufficient to cover it to a depth of 7,500 feet (Delesse). The lower estimate is the later and may be regarded as of the greater value. The determination of the total quantity of underground water in existence, however, while a question of scientific interest, is of no practical moment, since only a very small proportion of the total is accessible to man and can therefore be made use of by him. And again, of the relatively small amount that is within reach, only that proportion that, if withdrawn, will be restored annually can be utilized, because, obviously, withdrawals in excess of this mean reduction of the principal and eventual bankruptcy.

Hence, although impressive estimates of the total may be made—as, for instance, the statement that there are 600 cubic miles of potable ground waters beneath the State of Florida, 800 cubic miles in the Great Central Valley of California, 1,000 cubic miles in the Dakota sandstone aquifer, and 10,000 cubic miles in the sediments of the Atlantic and Gulf coastal plains—these statements are not merely valueless, they are sadly misleading, because, if issued without explanation, the inference would follow that such a tremendous amount of water could be extracted from these districts and used by man. This inference is wholly unjustified for a number of reasons. In the first place, only a limited although variable percentage of the water that saturates those parts of the rock or soil masses that are within reach of pumps can be extracted in development; the remainder, much the larger proportion, being capillary and subcapillary, is not capable of extraction in any commercial way.

Again, these estimates of total ground waters include those at great depth, utterly beyond the reach of any pumps or known devices for their recovery. And, finally, of the very small proportion of the total that can be brought to the surface and made useful to man, only an amount should be taken out that is equal to the annual restorations; otherwise there will be a gradual depletion of the supply and a corresponding increase in the cost of the product. Hence, as a practical people, we are not in the least concerned with the total quantity of ground waters, but only with the possible annual accessions to the total, for this controls use.

USE.

The use of ground waters in a limited way for domestic and farm supplies is well-nigh universal. Municipal use, although not so general, is also extensive; whereas use for irrigation, confined, of course, to the arid and semiarid States, has begun to attract attention only since power development, either by the utilization of the energy of running water or by means of small power plants of the steam or internal combustion type, has become general. With the imperfect data at hand it is not possible to estimate the total volume of ground waters now used throughout the United States, but it is believed that in Florida at least 2,000 second-feet are developed and in California more than one-half as much. The development in these two States, therefore, representing as they do more than the average development in the East and the West, is about 3,000 second-feet. Florida and California include about 7 per cent of the area of the United States. If the development throughout our domain can be regarded as on the average one-half as intense as in these two States, the total ground waters used if united in one stream would equal twice the volume of the Potomac at Point of Rocks, Md., in 1906, with a drainage area of 9,650 square miles, or if a smaller factor is used and the average intensity of development be regarded as one-third that of the two States named, we reach the conclusion that the ground waters now in use would make a river the size of the Colorado at Yuma, Ariz., with a drainage area of 225,000 square miles. Expressed in still another way, this volume is equal to somewhat less than 1 per cent of the total stream flow in the United States. It is to be clearly understood that this represents only artificial development, a direct product of man's activity, and does not include the natural springs which represent the unassisted return of ground waters to the surface. To these is due a very large although undetermined proportion of the low-water flow of all our streams.

PRESENT TENDENCIES.

One of the late phases of the irrigation movement involves the use of ground waters for this purpose. This movement has been inspired by the success of certain communities that have developed such waters and reclaimed a large acreage by their use. The southern California communities, one-half of whose irrigation is accomplished in this way, illustrate what can be done. In the San Joaquin Valley development of this type is under way and will inevitably be greatly extended. Three hundred second-feet of ground waters are now used there; probably 3,000 second-feet are available and colonies are being continually established and individual settlers are constantly entering the valley who are reclaiming more and more acreage by the use of this resource. In other western valleys, as in Utah and in Arizona, development of the same type is under way. Among the famous ground-water districts is that of the Great Plains, east of the Rocky Mountains, underlain by the Dakota sandstone, that yields some of the largest flowing wells of the United States. Another important district includes parts of Minnesota, Iowa, and Wisconsin, beneath whose surface lie water-bearing beds older than the Dakota sandstone, but the beds are locally quite as important. In these latter States irrigation is not practiced, but the ground waters are of great importance as sources of domestic and municipal supplies. In the Eastern and Southern States, those of the Atlantic and Gulf coastal plains are most favorably situated in regard to their ground-water supplies and in them development is more intense than elsewhere in the East. Attention has already been called to Florida, in which nearly 2,000 second-feet of ground waters are developed, nearly one-half of this amount being used for irrigation and domestic purposes. Mississippi, Louisiana, and Texas have abundant underground supplies extensively drawn upon in certain localities, but capable of much more extensive use. Data are not at hand for estimating the amount withdrawn at present.

WASTE.

Attention is usually first centered upon the use of ground waters by the development of flowing wells in areas where they may be secured. The advantages of a supply of this type are many. The waters usually cost little, they are protected from contamination, the output is regular, at least until development becomes too intense for the supply, and the quality is constant. But in regions in which flowing waters are used for irrigation and may be procured at shallow depths the resource is often shamelessly wasted. More wells are drilled than are needed and the water is used during but a small portion of the year, but is nevertheless allowed to flow with consequent reduction of head and depletion of supply and often in addition direct damage to the lands upon which it wastes. This waste is not so serious in humid regions in which the loss is quickly replaced by rainfall, but it goes on with equal recklessness in arid and semiarid sections in which the damage is irreparable. This waste is often in direct violation of state statutes, framed especially to prevent it. Where ground waters do not flow out upon the surface but are developed by pumping, waste does not take place, since the cost of production regulates automatically the amount of water withdrawn. Irrigation practice under these conditions is always superior, as the water user, paying for each gallon that he applies to his land, reduces this amount to the lowest effective quantity in order to save cost. Hence almost invariably better results are obtained with a lower duty in districts where irrigation water must be pumped than in those in which it flows.

In the humid regions ground waters—almost everywhere available—are particularly useful as sources of farm, domestic, and municipal supplies and for certain industrial purposes. They are especially beneficial and of particularly good quality in the coastal plain of the Atlantic and Gulf States and in the glaciated regions where the mantle of drift or of unconsolidated sediments forms a reservoir of great capacity, whose supply is rapidly renewed when drawn upon because of the abundant rainfall. Outside the coastal plain and the drift-covered areas conditions are variable, but generally they are inferior to those in the regions named, because the soil mantle over the rocks is often thin and irregularly distributed and in addition is frequently clayey and of small holding capacity. Within either of these regions there may occur synclinal basins of porous rock like the St. Peter sandstone and associated beds in Minnesota or the Dakota sandstone in the Great Plains, both of which form most important reservoirs. Usually, also, the fractured upper surface of whatever rock lies immediately below the soil carries a supply that may be drawn upon by town and farm wells.

IMPORTANCE.

The importance of these supplies in humid regions to the dwellers there is illustrated by Mr. Frank Leverett's careful determination of the fact that 75 per cent of the population in Michigan are directly dependent for water upon the underground supply, and since the constancy of the lakes and the flow of the streams upon which the remaining 25 per cent depend is also related to the ground waters, the importance of these is really greater than the given percentage indicates. A recent investigation of 19 counties in north-central Indiana again indicates the vital relation that ground water bears to daily life. Of 54 communities in these 19 counties having public supplies, 45 use wells alone and 3 others use both streams and wells. The urban population is therefore largely dependent upon the subsurface supplies and the rural population depends almost entirely upon them. It is estimated that in Florida 750,000,000 gallons of ground waters are used daily for town and country domestic supplies, while an additional 11,500,000 gallons are used by the cities and 500,000,000 gallons for the irrigation of tobacco, citrus fruits, and vegetables. One-half of the irrigation and the greater part of the city supplies in southern California, amounting to more than 300,000,000 gallons daily, are drawn from the sands and gravels that underlie the valleys, while in central California a smaller but nevertheless important draft is made upon the same source.

These available facts, selected from widely scattered localities, indicate clearly that in addition to the almost universal dependence of the rural population upon underground waters for culinary and domestic purposes, an important and growing use is made of them for irrigation and for town supplies. It is probable that it would be safe to apply percentages but slightly less than that determined in the State of Michigan to the entire United States, and to state that nearly 75 per cent of our population depends directly upon underground waters.

RELATION TO STREAM FLOW.

The indirect dependence of mankind upon ground waters is difficult to determine. The greater part of the low-water flow of those of our streams that have no large lakes, swamps, or glaciers in their drainage basins is sustained by the slow escape from soil and rock and vegetable mulch of water that is stored there during rains and the melting of snow. An amount equivalent to the low-water flow is also contributed of course during high-water periods, so that only that part of the annual run-off of ordinary streams that is represented by the excess of flood flow over low-water flow is discharged directly from the surface, without joining the body of the percolating waters. The remainder, for a longer or shorter part of its journey from the clouds to the sea, has been stored underground and the rate of its seaward passage thereby notably checked. The greater the proportion of precipitation within a drainage basin that joins the underflow, therefore, the more regular the streams of that basin. Areas of little or no underground storage are areas of violent floods and extreme droughts, while areas with a large proportion of underground storage are areas of slight floods and large and well-sustained low-water flow. Hence as a national policy all should be done that can be done to increase underground storage.

The factors that affect it favorably or adversely are many, and too few of them are within the control of man. Hence those that he can control should be used to the best possible advantage. Among these controlling factors are the character of the precipitation, the topography, including the steepness of slopes and of stream channels, the geology—that is, the character of the rocks and the soils—and finally the vegetation.

If the precipitation is violent and is concentrated within a short period, much less opportunity is afforded for its absorption than if the rain falls gently for a longer period. Brief violent storms are characteristic of our deserts where destructive floods are followed by long-continued droughts.

The effect of the topographic character of a drainage basin is obvious. There will be relatively little run-off from a perfect plain if the rocks or soil beneath it have absorptive capacity. In a region of steep slopes and stream channels of high gradient, on the contrary, water does not stand, and a comparatively slight precipitation will be followed promptly by a notable run-off, unless other favorable factors serve to prevent it.

The influence exerted by geology is also a powerful one. The type of rock, the presence and depth or the absence of soils derived from it, and the existence of a mantle of glacial drift often make the difference between a region well supplied with ground waters and drained by streams of regular flow and a region without ground waters and with most erratic and uncontrollable streams. Loose sandstones absorb water like sponges, to yield it slowly at some lower point, perhaps in a distant drainage basin. Cavernous limestones may offer tortuous underground passages through which water escapes slowly; the loose heaps of glacial débris permit but little surface escape, so thoroughly do they absorb the water that falls upon them. The deep mantle of decayed rock that covers many of our Southern States is equally effective in this respect. Polished glacial surfaces, on the contrary, such as exist in parts of the Sierra, shed water as effectively and promptly as a roof. Dense slates, fresh and unfractured granites, or close-grained metamorphic rocks absorb little or no water and contribute practically nothing to the underground supply.

Finally, the various cover growths are of the utmost importance in modifying absorption and run-off. Trees, brush, grasses, and growing crops act in many ways to this end. Everywhere the roots, penetrating the soil and decaying there, leave little channels for the circulation of the water; on mountain slopes and rocky areas they hold loose fragments of rock by their binding root systems and prevent them from being washed away so soon. The crevices about the rock fragments which are thus held become little storage reservoirs. The trees aid in making these crevices by the prying action of their roots and by the disintegrating action of the vegetable acids that are yielded by their decay. The various growths build up a porous absorptive soil by the litter which they shed and the rock sand which becomes enmeshed in their roots, and they protect the soil which thus accumulates and prevent it being swept away. Finally, they interfere directly with run-off by the obstacles which their roots, stems, and fallen leaves and branches offer to the flow of water over the surface. In all of these functions the immediate escape of rains as sudden floods is checked and their absorption, to be slowly released later, is encouraged. It is because of the full recognition of this part that forests play in the conservation of ground waters and the regulation of run-off that engineers and geologists who have made a special study of ground-water supplies and their relation to surface waters are such earnest advocates of the conservation and extension of forest cover.

LIMITATIONS AND METHODS.

Something has been said of the wide extent of ground waters, of their enormous aggregate volume, of the direct dependence of man upon them, of their critical relation to the more obvious stream flow, and of the growing recognition of their latent value and industrial possibilities. A word should be added as to the danger of exaggerating their utility or their practical quantity in some places and the complex problems involved in their utilization.

They are ultimately dependent upon rainfall. Therefore, like surface waters, they are less abundant in arid than in humid regions, and when used there they will be less rapidly renewed. But because of the greater need more attention is paid to them in the dry than in the wet States; they are more vigorously developed there and there is more danger that they may be overdrawn.

Many gravel-filled valleys west of the Rocky Mountains contain both surface and underground waters, not enough of either alone to irrigate all of the tillable lands, but when both are used together much more valuable than when either is used alone. Often power can be developed upon surface streams and this power applied to the recovery of the earth waters that saturate the lower valley lands. This mountain water coming down to the lands from above is made to lift the underground water to the lands from below—a most admirable combination and one excellently illustrated in the case of the Santa Ana River in southern California.

A part of the water of this river is stored in a reservoir in the San Bernardino Mountains and the flow of the stream thereby regulated. After it escapes from the reservoir it is diverted through a power plant and electric power is generated. Below the first power plant it is rediverted and passed through a second power plant. Below this it is all distributed and used for municipal and irrigation purposes about Redlands and Highlands. The waters that return from the irrigation are recovered in springs and flowing wells and by pumping plants, a portion of the power developed higher up on the stream being used for the latter purpose. This recovered water is used for irrigation about San Bernardino and Riverside. A part of it reappears in the river above Riverside Narrows, where it is again taken out into a power ditch whose waters are returned to the river above Corona. A few miles below it is picked up by canals and distributed to the orange and deciduous groves about Anaheim and Santa Ana. The portion of it that returns there, by irrigation, to the ground water is once more recovered by the many pumping plants and flowing wells west of Santa Ana in the lower coastal plain.

A single drop of water in its progress from the mountains to the sea, a distance of only 100 miles, may thus be used as many as eight times for power and irrigation. This is an almost ideal use of water. The combination of power development and the recovery of underground waters to supplement the surface flow results in a minimum of waste and a maximum of economy. Development of this type is being rapidly extended now over parts of the West and will receive still further extension in the future.

But care must always be taken not to tax too severely the underground basins from which the water is drawn. They are not by any means inexhaustible. When rainfall is light, the quantity of water returned to the reservoirs each year may be small, although the quantity stored there is large. However large it may be, if more is withdrawn each year than is replaced, there will be gradual lowering of the ground-water level and ultimate disaster. Therefore, users of ground waters in arid regions must study carefully the effects of development in order to be sure that they are not prospering during the present at the expense of disaster in the future. Furthermore, in many sections where water is badly needed ground waters do not exist. Residents of such sections, urged on by their need, do not always realize this, and attempts that are hopeless from the beginning are made to procure them. Each field is a particular problem with its own solution. General rules have only a limited application.

RELATIONS TO OTHER RESOURCES AND TO CONSERVATION.

Ground waters and surface waters are, of course, intimately related. All usable ground waters were first surface waters, although perhaps only momentarily, and the greater part of them eventually become surface waters again after their journey underground is completed. It is thus that they sustain stream flow during dry periods and so are closely related to power development and to irrigation, both of which are much more successful with a sustained and regular than with an erratic run-off.

Practically all vegetable life depends upon the existence of ground water. It sustains our crops and our forests and is in turn protected by them through functions already outlined. Seventy-five per cent of our population depends directly upon it, and an important additional percentage indirectly. It is used in irrigation, in industry, in transportation, in all the many activities of life. But, being one of the resources that is constantly renewed by natural processes, we need only exercise reasonable care in our use of it to have it to draw upon perpetually. There are districts in the United States, fortunately few in number and small in area, where the ground waters are being extracted faster than they are renewed. There are other areas in which they are being contaminated and rendered useless or harmful by the careless discharge of industrial waste or sewage or brines from deep wells. There are still other areas in which, through the stripping of the natural cover growths, the annual accessions to the supply are materially reduced. These conditions must be met and remedied; then nature, through her annual rainfall, will repair the harm, as yet slight, that has been done.

FLOODS.

By M. O. Leighton,
Chief Hydrographer, United States Geological Survey.

A broad and comprehensive review of river-discharge records in the United States indicates unmistakably that floods are increasing. It is true that the opposite tendency may be shown on some rivers, while the records on others may indicate little or no change; but, taken as a whole, the rivers that reveal more intense flood tendencies so thoroughly dominate the situation that the conclusion above expressed must be inevitable.

It will be well to consider at the outset just what index may be used to determine the trend of flood tendencies. It is common in inquiries of this character to select and compare the highest stages attained in the several years of record, and because, perchance, higher floods may be shown in early years, many really competent persons have believed themselves forced to the conclusion that there is no increase in flood tendency. The actual height attained by the maximum flood each year is, however, a matter of small consequence in such considerations. A little reflection will show how this must be true. The precipitation, which is the ultimate cause of floods, takes three courses, only two of which are really important in the present discussion, namely, the course along the surface of the ground directly into watercourses, and that into the ground by percolation, with subsequent discharge into the rivers by seepage. In general terms it may be stated that the water which causes floods is that proportion of the precipitation which the earth does not absorb and which, therefore, must flow along the earth's surface. Now it is apparent that when precipitation becomes so intense and long continued that it practically saturates the ground the rain that falls thereafter must take the direct route and floods must necessarily arise. Therefore the height of great floods is fixed primarily by the intensity of precipitation and, as the amount of rain varies from year to year, now bountiful and again scanty in what seem to be fairly uniform cycles of years, the observation of an especially high flood during an early year compared with that of a much lower one during a recent year can give no index to flood tendency in any river. The real index is of more fundamental origin than the mere occurrence of high floods.

When the question "Are floods increasing?" is asked, the considerations involved are not those of height but those of duration and frequency. In other words, the question means, Are floods of more frequent occurrence and are there more days of flood than formerly? Reverting for the moment to the discussion in the foregoing paragraphs, it is plain that floods will occur more frequently in response to a given rate of precipitation, if there are in the drainage area influences that either inhibit or prevent the ready absorption of the rain by the ground, than they would if absorption were ideal. Such ideal condition assures complete absorption of all precipitation. A rain of a given depth in a unit's time—say 2 inches in one day—would surely produce a flood in a drainage area which was nonabsorbent. On the other hand, the same amount of rain would not change the river stage if the conditions enhancing absorption on the drainage area were ideal. Between these two extremes there are wide and varying conditions which tend to increase or to diminish the resultant floods from a given rainfall. In other words, the question "Are floods increasing?" means, essentially, Are the conditions of the surface of the ground in the river basins so changing that they render the ground less absorbent? If this be the case, it is clear that a much larger proportion of the precipitation would run directly off into the rivers than that which was so conducted at an earlier period.

There are five classes of agencies or conditions affecting the flow of streams. The first is climate, under which are comprised rainfall, evaporation, temperature, wind, and humidity. Although these are exceedingly variable from day to day and from season to season, the observations that have been recorded indicate that a period of years embraces all conditions, so that the mean of them may be considered fairly constant. There is very little evidence, except in special areas, that reveals any progressive and permanent change in climatic conditions. The second agency is topography, and the third geology, both of which may, for present purposes, be considered absolutely stable. The fourth is surface vegetation, which includes forest cover and cultivated land. This is subject to progressive change, according to the demands, conveniences, and usages of society. The fifth consists of artificial agencies, such as storage, reservoirs, and drainage, which produce rapid and marked effects on river discharge.

Therefore, the consideration of river discharge and especially of floods involves the appraisal of the effects of climate, vegetation, and artificial agencies. The other two agencies, being constant, may be left out of consideration. It is necessary to take account of these conditions in connection with all studies of progressive flood trend. This emphasizes the futility of many studies that have heretofore been made, in which not only have the extreme flood heights been the basis of determination, but there has been a total lack of consideration of climatic conditions, especially that of rainfall. A river, for example, may show a progressive decrease in flood frequency during a period of years. If that were taken alone it would indicate a decreasing flood trend; whereas, if the rainfall be compared progressively in the same manner, it might readily be shown that the flood trend was increasing rather than diminishing, because the precipitation was decreasing faster than the flood frequency.

The above considerations have been kept in mind in the study of flood frequency here presented. The accompanying diagrams, Nos. 1 to 8, inclusive, are the result of appropriate studies made of flood occurrence on rivers on which gages have been maintained for a long period, the longest, in fact, of which there are available and useful records in this country. Examination shows conclusively the increasing trend of flood occurrence and the cause thereof comes now properly into question.

As already stated, the rainfall, which is by far the most important of the climatic conditions, has been accounted for in these diagrams, and we have, therefore, remaining only the condition of the ground surfaces in the drainage areas and artificial agencies. For each of these rivers artificial agencies may be eliminated. Our general knowledge of conditions on the drainage areas gives assurance that there has been no reservoir installation of extent sufficient to modify in the slightest degree the normal conditions of flood discharge. This is also true with respect to artificial drainage.

Therefore we come down to the condition of the land surface, or, as above expressed, conditions of vegetation. We are aware that on all of these drainage areas there has been progressive cutting of timber and building of roads. The latter improvements, however, have not been of sufficient extent to modify in any appreciable degree the discharge. A computation of the actual road areas, including the paved streets, etc., will show conclusively that, in comparison with the total area under consideration, they are insignificant. The conditions of cultivated fields undoubtedly have a marked influence in modifying the rate of river discharge, and it is certain that some of the effects in these areas are due to this cause. The cultivation of fields has, however, improved markedly in recent years. The farmer has learned to a considerable degree that it is more profitable for him to cultivate his inclined fields by contour or terrace cultivation, and a cursory view of the areas represented in the accompanying diagrams will show that to a very large extent improved methods of cultivation have been put into effect.

Altogether, when the physical conditions on the drainage areas are summed up, the one great change that has been produced in the vegetative conditions is the reduction of forest area. On some of these drainage areas it has occurred by slow progression and on others more rapidly. It is certain that in some areas this forest cutting has caused barren conditions, because the land was of such a character that, after it was relieved of forest protection, it eroded easily and its productive portions were quickly swept into watercourses.

Summarily, therefore, it may be stated with confidence that the increase in flood tendency shown so unmistakably is due in by far the largest measure to the denudation of forest areas.

Diagrams 1 to 4, inclusive, are expressions of progressive changes in flood occurrence during the series of years indicated thereon. They are all drafted on a uniform basis, the first expression in each case being a record of the annual precipitation in inches; the second gives the number of days in each year that the gage at the point designated registered above a certain stage; the third is a combination of the first two and gives the relation of the number of days of flood to the precipitation. Thus, there is given in one expression the actual trend of flood occurrence in terms of precipitation. This form of expression eliminates one variable in the conditions governing flood occurrence, and the only remaining ones to be considered are vegetation and artificial agencies, as discussed in previous paragraphs.

The second series of diagrams on each sheet gives the same relations except that the amounts are united into progressive decades, or in one case into progressive five-year periods. This form of expression serves to neutralize the variability that occurs in the successive years and gives to the whole diagram a progressive trend which is more comprehensive and more easily interpreted than the statement of actual amounts. Thus, in sheet No. 1, the first progressive period covers the interval from 1885 to 1894, the second that from 1886 to 1895, and so on, each period representing ten years, and the total amount of rainfall and the total number of days of flood for each decade is expressed, rather than the average amount of these quantities.

In interpreting diagrams of this kind it should be emphasized that the amounts actually shown are not significant, save as they indicate the relative trend of the successive decades. In other words, the diagrams indicate direction, and should be so interpreted.

The data given on the above-mentioned sheets relate to the upper Ohio drainage area, and they show the relation of flood occurrence on the three principal tributaries thereof—the Allegheny, Youghiogheny, and Monongahela rivers—to flood occurrence on the Ohio at Wheeling. It will be seen that in each case there has been a marked increase in the number of days of floods, and the four diagrams can be consistently compared. At Wheeling during the period 1885 to 1907, inclusive, the ratio of flood occurrence to annual precipitation increased from 0.38 in the first half of the period to 0.48 in the second half, and this relation is shown more distinctly in the similar expression with the amounts given in totals for progressive decades. The gage records on the Allegheny at Freeport, Pa., show an increase in this ratio from 0.86 in the first half to 1.04 in the second half of the period 1874 to 1907, inclusive. The Monongahela record shows an increase of ratio during the period 1886 to 1907, inclusive, from 0.49 in the first half to 0.55 in the second half, while a still greater divergence is noted on the Youghiogheny, the ratio for the period 1875 to 1906, inclusive, increasing from 0.35 in the first half to 0.47 in the second half.

Altogether, these diagrams are extremely significant in showing the progressive increase in flood occurrence on a drainage area the deforestation of which has been constant and rapid for the past thirty years. It began first on the Allegheny and the results are apparent in the diagrams. Subsequently, timber cutting began on the Monongahela and Youghiogheny areas and is occurring at the present time.

Similar results are shown on sheets Nos. 5 to 7, inclusive, which give the same data for Wateree River above Camden, S. C., the Savannah above Augusta, Ga., and the Alabama above Selma, Ala.

Sheet No. 8 is a record of flood duration on Connecticut River at Holyoke, Mass. This river basin has been subject to continuous deforestation for a long period. Recent testimony shows that for the last twenty years from 50,000,000 to 80,000,000 feet B. M. of timber have been released over the dam at Turners Falls annually. Records of private logging are not available, but it is known that the deforestation of the drainage area commenced some time previous to this period.

There is one point of objection that may reasonably be taken to the diagrams above discussed. It is that they draw comparison between annual precipitation and the number of days of flood. A better comparison would be one between the number and depth of flood-producing rains and the number of flood days. Such a comparison has been made on the Tennessee basin above Chattanooga. No other basins are here dealt with in this way because of the enormous amount of labor involved.

In addition to proving beyond controversy the increase in floods due to deforestation, the record is of interest because it shows how futile and misleading is the attempt to derive conclusions from flood records without taking into account records of precipitation. Inspection of the Chattanooga flood record shows a decided decrease in the number and duration of floods during the period of record. If this were taken alone, it would controvert the forest-control idea. A comparison of the precipitation records on the drainage area, however, assures us that the rainfall has decreased, even to a greater relative extent than the floods. The final result is that the flood tendencies have increased.

The results for the Tennessee basin cover 24 years, from 1884 to 1907, inclusive. Although the records of gage height extend further back than the earlier date, the number of rainfall stations maintained on the basin previous thereto is not sufficient to render safe any conclusions with reference to precipitation. It is appreciated that a given depth of rainfall precipitated during the winter months will generally produce a greater run-off than the same depth would produce in August or September. Therefore an effort has been made to eliminate this source of error. Summing up the flood-producing rains for the 24-year period it is found that the total is 335, of which 313 occurred from December to May, inclusive, and the remaining 22 during the other portion of the year. It is apparent that the number of such rains from June to November is not sufficient to afford a basis of comparison. Therefore only the December to May floods will be considered. In making this comparison the ideal condition would be to compare the rainfalls and floods during identical conditions of climate, but such a refinement is impossible. On the other hand, the multiplication of data afforded by the large number of flood-producing storms in the December to May periods warrants the conclusion that the varying climatic conditions in this period are compensated, and the final conclusions drawn from the result must be worthy of confidence. On dividing the period covered by these 313 floods equally, two consecutive 12-year periods are afforded, which give a basis of comparison. The floods in the later period, resulting from a given depth of storm precipitation, are clearly shown to be more severe than in the earlier period. The method of presentation further makes it possible to compute the increase in flood tendency due to deforestation in the Tennessee.

The relation between storms and floods in the Tennessee basin during the periods December–May, inclusive, 1884–1895 and 1896–1907.

Period.	Storms in inches precipitated.											
	1 to 1.5.		1.5 to 2.		2 to 2.5.		2.5 to 3.		3 to 3.5.		3.5 to 4.	
	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.
1884–1895	7	5	12	6	6	15	5	9	5	13	6	30
1896–1907	8	3	11	10	9	23	11	30	4	13	1	6

Period.	Storms in inches precipitated.											
	4 to 4.5.		4.5 to 5.		5 to 5.5.		6 to 6.5.		7 to 7.5.		8 to 8.5.	
	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.	Storms.	Days of flood.
1884–1895	1	6	2	17	2	18	......	......	2	28	......	......
1896–1907	1	8	3	20	......	......	1	11	......	......	1	17

If we now divide the number of flood days by the number of storms, the result will be the number of days per storm. Applying this to each of the series in the above table, the following result is reached:

Days of flood per storm.

Period.	Storms in inches precipitated.							
	1 to 1.5.	1.5 to 2.	2 to 2.5.	2.5 to 3.	3 to 3.5.	3.5 to 4.	4 to 4.5.	4.5 to 5.
1884–1895	0.7	0.5	2.5	1.8	2.6	5	6	8.1
1896–1907	.4	.9	2.6	2.7	3.2	6	8	6.7
Percentage increase	−43	80	4	50	22	20	33	−17

The algebraic sum of the above percentages is 149.00 and the average is 18.75, which sums up the effect of deforestation on run-off from 1884 to 1907, inclusive.

FLOOD DAMAGES.

A complete census of flood damages for any year or series of years has never been attempted. Therefore, it will be impossible to present any figures for which precision may be claimed. The damages for particular floods in certain areas have from time to time and for one or another purpose been assembled and, in a few places, examinations have been made with great care by commissions and boards especially qualified for such work. The results of such examinations may be taken to form a basis for an estimate; but, for the present purpose, a better basis has been made available. During the present year the Geological Survey has made inquiry of all the railroads in the United States concerning flood losses during the period January 1, 1900, to August, 1908. The railroads were selected for this purpose because it is well known that they are, by reason of their location and extent, subject to far greater physical damage than any other single interest, and it was believed that from the figures so procured a fairly representative basis of estimate might be obtained. From previous studies of this matter it appeared that the railroad losses resulting from floods amount to about 10 per cent of the total physical loss arising therefrom, excluding, of course, the largest single item of loss, which is the depreciation of realty values arising from flood menace. The figures here presented will therefore exclude all consideration of this kind of loss.

The proportion of 10 per cent was arrived at from three points of view:

First. It has been the observation of the writer that, as a rule, the reported losses to railroads from floods have amounted to about this proportion.

Second. The actual investigations of flood losses, made by appraisal boards, and individual property returns covering fairly wide areas have approximated this proportion. Undoubtedly the most complete and comprehensive investigation of this kind was carried on by the northern New Jersey flood commission in 1903, after the great flood that arose in October of that year along Passaic River. The region comprehended in this investigation may be considered a typical one. It comprised the usual proportion of farm lands, city areas, highway bridges, railroad property, etc., and the proportion of railroad loss there was almost exactly 10 per cent of the total.

Third. One-tenth of the wealth of the United States consists of railroad property. This proportion was therefore used in the following estimates.

During each of the periods above named the returns from the railroads involved a varying percentage of the total mileage of the country. The mileage involved in each yearly estimate has been expressed as a percentage of the total mileage for that year, as given in the reports of the Interstate Commerce Commission. The several amounts were increased from the percentage that they represented to 100 per cent, to cover the entire mileage of the country. Inspection of the returns showed that this was a fair and reasonable method, because the reports were well distributed and represented a true proportion of that which might be expected to be the damage on the total mileage. This figure was then considered as 10 per cent of the total damage for the whole country and increased accordingly. The results are given in the following table:

Year.	Damage reported.	Percentage of total mileage reported.	Total railroad damage.	Estimated total damage.
1900				
1901	$666,253	14.6	$4,567,500	$45,675,000
1902	958,740	21.1	4,543,800	45,438,000
1903	1,225,468	22.2	5,520,100	55,201,000
1904	2,654,192	27.3	9,722,000	97,220,000
1905	2,476,724	31.3	7,884,100	78,841,000
1906	3,286,324	33.3	9,858,972	98,589,720
1907	2,727,511	37.3	7,312,400	73,124,000
1908	4,623,106	39.1	11,823,800	118,238,000
	6,517,577	27.4	23,786,000	237,860,000

STORAGE OF FLOOD WATERS.

In the northeastern portion of the country there has been a large installation of reservoirs and a consequent saving of enormous amounts of flood water. The numerous lakes in that part of the United States, irrespective of those that have been developed artificially, have a beneficial effect. It is probable that 10 per cent of the flood waters that originate in New York and New England are saved by storage in artificial reservoirs, lakes, and ponds. In Minnesota, at the head of upper Mississippi River, practically the entire flood drainage from an extensive area is conserved. In the arid West there has been an extensive installation of reservoirs, some of which conserve practically all the flood waters on their respective basins. Considering the country as a whole, however, it is doubtful if more than 1 per cent of the flood water is saved.

The storage of floods is effected by forests and similar surface vegetation and by artificial reservoirs. The amount stored by forests is and probably will for a long time to come be indeterminate, since the forest is merely an agent in assisting the ground to absorb the water. The storage is therefore essentially ground storage and the ability of the forest to enhance this is dependent absolutely on the character of the soil beneath the forest. Therefore, to fully answer the question, "To what extent could flood waters be stored by forests?" it would be necessary to consider minutely the absorption properties of the various kinds of land surface in the United States. It will be possible at some future time to give an approximate and exceedingly useful reply to this question; but before that time arrives we must have more long-term gage records on our rivers. The diagrams presented with this paper (sheets Nos. 1 to 8, inclusive) constitute as useful records as there are extant in the country, and a short consideration of them will plainly reveal the fact that, while they are exceedingly useful in indicating the trend of flood duration and frequency, they do not yet yield sufficient information to give even the widest approximation of the amount of water or the proportion of run-off that can be conserved.

The question is therefore one for the future, and our stream investigations should be carried on with this as one of the purposes in view.

The extent to which flood waters could be stored by reservoirs depends on the available reservoir capacity in the several river basins. As a rule, the more diversified the character of these basins, especially in contour, the greater facilities they afford for reservoir storage.

There is a great portion of the Mississippi Valley in which floods are not subject to correction under the reservoir plan. This is also true of certain coastal-plain streams like the Brazos and Colorado. It is probable that the streams draining one-third of the area of the United States must forever be subject to floods, and the only treatment that now appears feasible for these streams is the construction of levee systems. For the remaining two-thirds of the United States, investigations so far made indicate that from 55 to 60 per cent of the flood waters can be saved by the utilization of maximum storage capacity. Although the cost of such construction would be enormous in the aggregate, it is apparent that the saving that would accrue from relief from flood damages alone would soon return the entire investment. A glance at the estimated flood damages in the United States, page 109, shows the possibilities. In this connection it should be stated that in by far the larger proportion of the basins a saving of 55 to 60 per cent of the flood waters would insure practically entire relief from flood damages. It is not necessary to prevent floods absolutely; or, in other words, it is not necessary to secure uniformity of flow in any river in order to secure relief from flood damages. The construction of the reservoirs necessary to prevent floods would, under proper management, involve an increase in the water-power possibilities of the United States equal to about 60,000,000 horsepower. In the arid West the construction of reservoirs for flood prevention would provide water sufficient for the reclamation of many million acres of now worthless land. All of this, together with the assistance that such reservoirs would lend to navigation, constitutes the saving that would accrue from their construction. We are unable at the present time even to approximate the total figure, and therefore it must be summed up in the term "vast."

RELATION OF SURFACE CONDITIONS TO STREAM FLOW.

By WM. L. HALL and HU MAXWELL.
U. S. Forest Service.

Popular opinion for years has been that floods are increasing in frequency and duration in many rivers of the United States. Until within a year, however, there had been no careful examination of records to see whether or not the popular opinion is based upon fact. The scientific bureaus of the Government which are directly interested in the matter had assumed that records had not been kept long enough on any river to show a change in the conditions of flow. As late as September, 1908, Col. H. M. Chittenden, of the Engineer Corps of the Army, in a paper presented before the American Society of Civil Engineers, said:

> The constantly reiterated statement that floods are increasing in frequency and intensity, as compared with former times, has nothing to support it. There are, it is true, periods when floods are more frequent than at others, and hasty conclusions are always drawn at such times, but taking the records year after year for considerable periods no change worth considering is discoverable.

About a year ago it was thought worth while to look into the records to see whether any changes were discernible. The results were surprising. It was found that in many of the streams which take their rise in the Appalachian Mountains there has been a steady increase in the number and duration of floods during the past twenty or thirty years.

Following this discovery, a very general study was made of the change which has come about in the flow of a number of important rivers during the time for which records have been kept. Both the Geological Survey and the Forest Service have presented data on this subject during the year, and the results of both warrant the statement that unmistakably floods are steadily on the increase in some of our most important rivers.[a] Particularly is this true of the rivers which rise in the eastern mountains. The increases seem to be greater on those watersheds where the condition of the surface has been the most changed. They are greatest in such streams as the Ohio, Cumberland, Wateree, and Santee, where the most forest has been destroyed, and least on the streams where forest conditions have been least changed.

It is true that in certain rivers an opposite tendency is to be seen. Floods have decreased and low waters have markedly improved. But a full inquiry into the conditions on these rivers also, as will be shown, seems to prove the rule that there is the closest kind of relationship between the surface conditions of a watershed and the flow of water through the stream which drains it.

The following table gives records regarding the flow of 10 important rivers of the United States on which careful records have been kept for periods ranging from sixteen to thirty-four years:

---

[a] Floods in the United States, by M. O. Leighton, Chief Hydrographer, U. S. Geological Survey. Paper prepared for National Conservation Commission.

Flood and low-water records for 10 important rivers.

a Increase.

b Decrease.

THE TENDENCY IS TOWARD INCREASED FLOODS.

If the period during which the records have been taken on each of these streams be divided into two equal parts and a comparison be made of flood conditions for those parts, we find that 8 of the 10 rivers show greater floods in the last half than in the first half. The 8 rivers which show increased floods are the Potomac, at Harpers Ferry, W. Va.; the Monongahela, at Lock 4, Pennsylvania; the Ohio, at Wheeling, W. Va.; the Cumberland, at Burnside, Ky.; the Wateree, at Camden, S. C.; the Savannah, at Augusta, Ga.; the Allegheny, at Freeport, Pa.; and the Tennessee, at Chattanooga, Tenn. All of these streams, it will be noted, have their source waters in the Appalachian Mountains.

On the Potomac River, for which measurements are given for eighteen years, the number of floods during the first half of the period was 19; during the second half, 26; while the number of days of flood in the first half was 33, and in the second half, 57.

On the Monongahela River measurements are given for twenty-two years. During the first half of the period there were 30 floods; during the second half, 52. The number of days of flood during the first half of the period was 55; during the second half, 100.

On the Ohio River measurements are given for twenty-six years. During the first half of the period there were 46 floods; during the second half, 59. The number of days of flood during the first half was 143; during the second half, 188.

On the Cumberland River measurements were given for eighteen years. During the first half of the period there were 32 floods; during the second half, 43. The number of days of flood during the first half was 89; during the second half, 102.

On the Wateree River measurements have gone on for sixteen years. In the first half of the period the number of floods was 46; in the second half, 70. The number of days of flood in the first half of the period was 147; in the last half, 187.

On the Savannah River measurements have continued for eighteen years. During the first half of the period the number of floods was 47; during the second half, 58. The number of days of flood during the first period was 116; during the second half, 170.

On the Allegheny River measurements are given for thirty-four years. During the first half of the period there were 39 floods; during the second half, 53. The number of days of flood during the first half was 92; during the second half, 131.

On the Tennessee River measurements have been taken for thirty-four years. During the first half of the period there were 32 floods; during the second half, 33. The number of days of flood during the first half was 173; during the second half (in this case there was a falling-off), 137.

Mr. M. O. Leighton, chief hydrographer of the United States Geological Survey, has during the past year made an elaborate study of the floods in the Tennessee River.[a] In this study Mr. Leighton has isolated so far as possible the days of rain storm of sufficient magnitude to produce floods, and on this basis has made a comparison of the floods of the two halves of the period. Although the number of days of flood was less during the last half of the period than during the first half, Mr. Leighton shows that the precipitation decreased in an even greater degree. The results of this close analysis show that the diminution of the precipitation has been more than sufficient to account for the diminution of the floods. The natural result is that in proportion to the rainfall, floods have increased, the percentage of increase being 18.75 in the last half of the period as compared with the first half. This study is undoubtedly the most complete and authoritative that has ever been made of any American river, and it seems conclusive.

---

[a] Floods in the United States, by M. O. Leighton, chief hydrographer, U. S. Geological Survey.

The low-water stages of a river are never a safe criterion on which to judge its real condition. A slight change in the bed of a stream may considerably affect the low stage at the point where the measurements are taken, though the real condition of the stream may not be changed in the least. In the same way a stream may actually raise its bed by silting, and thus the low-water stage may be increased while the actual condition is worse than at first. A study of the low-water data of the above table shows that intensified low-water conditions as signified by the measurements do not correspond in all cases with intensified flood conditions. Of the eight streams above referred to, four show apparently intensified and four apparently ameliorated low-water conditions. But for the reasons just stated, these records can not be depended upon as having any real significance in showing the actual flow.

The constant increase in the frequency and duration of floods in these streams appears not to be due to change in precipitation. In two cases there has been a slight increase in precipitation. These are on the Potomac watershed, where, as the table shows, there has been on the average 1.16 inches more rain in the second half than in the first half of the period. On the Wateree there was an increase of 2.02. On all of the other watersheds there has been a decrease ranging from 0.90 of an inch on the Monongahela to 6.34 inches on the Tennessee. It is thus clear that while floods have greatly increased in these streams the tendency has been toward decreased precipitation.

While the record is given for only eight streams which show increased floods, it must not be understood that these are the only streams which show this tendency; rather, they are examples—particularly they are examples of streams having their source in the Appalachian Mountains. They have been given because their records are more complete and longer than those for other streams. The records of most other streams of the region, so far as they are sufficient to show a tendency, indicate the same progressive change toward increased floods. For example, this is true of the Alabama River, of the Connecticut, of the Muskingum, and of the Congaree.

WHAT HAS CAUSED INCREASED FLOOD CONDITIONS?

Since it is apparent from the records that flood conditions have greatly intensified in many streams during the past two or three decades, it is important to consider the possible causes. Several factors are known to have an important influence upon stream flow. Chief among these are climate, topography, geology, natural or artificial reservoirs, soil, and ground cover. Climate must be understood as embracing precipitation and evaporation, with whatever influences them—notably, wind, humidity, temperature, and altitude. It is best to consider precipitation and evaporation separately, for they act in opposite directions and produce opposite effects.

PRECIPITATION.

It is, of course, apparent that precipitation must modify stream flow in a vital way, because no water can flow through the streams that does not first come down from the clouds. The amount of precipitation varies greatly from year to year. The amount for one year may be twice as great as for another in the same place, and at one point it may greatly exceed or fall short of that occurring a few miles away. While varying in a marked degree for short periods, precipitation becomes much more nearly constant through a long period.

If the precipitation had correspondingly increased over the Appalachian Mountain region, then it could be said that the greater and more frequent floods are due to that. But the figures which are given show that on only two of the eight watersheds mentioned in the table has there been any increase, and there by small amounts, while in the other six there has been a decrease, which in the case of one stream, the Tennessee, amounts to an average of 6 inches. The real tendency of the precipitation over these basins would therefore be to decrease flood conditions. Consequently, we must conclude that the increased flood conditions are in no degree due to precipitation.

EVAPORATION.

Taking the United States as a whole, less than half of the precipitation is said to pass through the rivers to the sea; the other part after a longer or shorter period, and after serving one purpose or another in nature's economy, goes back to the air through evaporation, except that portion which flows through underground courses to the sea.

Evaporation is fundamentally influenced by temperature, air pressure, wind, and humidity, and affects in a vital way both the regularity and amount of run-off of the streams. The Connecticut and Wateree rivers have about the same average annual precipitation—45 inches per year. Of this amount the run-off from the Connecticut watershed is 29 inches; from the Wateree watershed it is less than 18 inches. The difference is due to increased evaporation on the Wateree, where the temperature averages much higher. It is during the prolonged heated periods, which are often dry periods, that evaporation has greatest influence. It undoubtedly affects as much as any other factor the low-water stages of the streams, yet by its very nature it can not much influence floods, because they rise quickly and are never of many days' duration. There is not time for much water to evaporate. Hence we can put aside this climatic influence just as in this case we have put aside precipitation. We must look elsewhere for the cause.

TEMPERATURE.

Temperature, while influencing stream flow indirectly, through evaporation, also influences it directly. For example the upper watershed of the Monongahela River, in West Virginia, may be considered:

It is February, and there have been several weeks of cold weather; the ground, which is bare of snow, is frozen solid. There comes a heavy fall of snow, or perhaps several, bringing the snow cover to a depth of 12 to 18 inches. Within a few days the weather moderates and a prolonged rainy period follows. The first rain is caught by the snow and little escapes. But as it continues to come, it melts the snow so that the water from the snowfall and the rainfall is concentrated upon the surface at one time. If the ground were not frozen, much of it could be absorbed and distributed downward, but in the case we have assumed the earth is frozen solid, so that no water, or at least but little, can be absorbed. The whole volume is liberated on the surface and races away from the smaller streams to the larger, and at last, gathering in immense quantity, it overtaxes the channel of the main river and inundates the entire valley. It is this condition of rain, snow, and temperature operating together which brings about some of the greatest floods. A flood resulting from such a cause is not likely to occur more than once a year in any stream, and several years may pass without flood on a given watershed from this combination of causes. It can not be said that floods from this cause show any progressive change, and consequently we can not ascribe to this cause the increased flood conditions in the rivers now under consideration.

TOPOGRAPHY AND GEOLOGY.

A region's topography largely influences its run-off. Steep slopes and sharp ridges shed water quickly. A flat surface causes it to flow away more slowly.

Likewise, geology has a great deal to do with the drainage of any region. When rain has fallen and has passed through the soil cover and the soil, it comes in contact with the rocks which lie beneath. In obedience to gravity it will penetrate as deeply as possible. Considering the depth to which it can go and the quantity in which it can be stored, the earth forms a great storage reservoir which tends on most watersheds to have a strong influence toward steadiness in the flow of streams. While topography and geology are important factors in considering the amount and character of run-off, when one stream is compared with another, they are of no consequence when one is considering the condition in the same stream during two different periods, because they are subject to no appreciable variation. Both the topography and the geology of any given stream may be said to be constant, and so are not of importance in considering what has caused a changed condition of flow in any particular stream.

NATURAL AND ARTIFICIAL RESERVOIRS.

Some streams have on their watersheds great lakes which gather and hold immense volumes of water. A good example is the Merrimac River. On one of its important tributaries is that fine body of water, Lake Winnepesaukee; on another is Squam Lake, and, in addition, there are many smaller ones. Every natural reservoir of this kind tends to equalize the flow of the stream it feeds, because when its level is rising it is gathering in storage to pay out gradually the water which would otherwise run off at once. Moreover, on many of the lakes, espectially on those in New England, dams have been built at the outlets. By this means the water of the whole surface has been increased a number of feet in depth. In dry times when it is needed this water is emptied out. A large portion is thus taken off of the crest of each flood and added to low waters. Then, too, men may construct reservoirs where there were none before. It is considered feasible in some streams to construct such extensive reservoir systems as to store a large part of the flood waters. If this can be done, the flow of the streams can be made for all practical purposes even throughout the year.

If at the headwaters of the rivers under consideration in this paper there had been great lakes or swamps which had been drained during the period under consideration, it might well be said that the influence of that action would be sufficient to cause a difference in the run-off of the streams. But, except in the case of the Wabash, there have been no changes of this character. There are on these streams no important natural lakes, and no reservoirs of great extent have been developed. Consequently, this factor also is insignificant.

SOIL.

Though the topography and geology of a watershed change too slowly to be readily observed, there are other factors in which changes may be rapid, radical, and of great importance. One such factor is soil. The soil, when considered as a factor in controlling run-off, is a complicated and delicate apparatus. It works admirably when in good condition, but it is easily deranged and is liable to severe and fundamental injury, by which its action on storm water may be lessened or almost entirely destroyed. Mistreatment frequently produces results of a serious nature in the drainage of a watershed.

The mineral soil is composed of disintegrating rock that has broken down by the slow process of weathering. Deep mineral soils, if they have not accumulated from transported materials, represent a long period of rest, during which the surface has been free from erosion, while the disintegrating rock beneath has added little by little to the depth. Upon the mineral base, and more or less mixed with it, is the humus, which owes its existence to organic matter mostly vegetable, which has decayed and added the accumulated remnants to the mineral soil. Humus vastly increases a soil's capacity to absorb and store water.

The important work which soil performs in regulating the run-off for a region is easily understood. If the soil is present in sufficient quantity and good condition; that is, is porous and well supplied with humus, it readily absorbs storm water at the surface and passes it on downward through the underlying rocks and strata. Although these rocks themselves change but little, their storage of water is regulated by the soil and varies with its changes. If the soil is hardened or removed, the amount of water which can be taken in is correspondingly reduced, and the amount which is thrown off over the surface into the streams correspondingly increased. A watershed without soil or with a soil which does not readily perform its normal functions, results in erratic streams, which are usually agents of destruction rather than of use. The consideration of the flow of any stream should therefore take particular note of the soil and of the changes in its capacity for water storage.

GROUND COVER.

Scarcely separable from the soil itself is another factor of equal or greater importance in the disposition of water. This is the ground cover, or, to speak of it more particularly, the condition of the surface of the ground; that is, whether it is barren rock or clay, pasture land, cultivated land, or forest.

The condition of the surface does not influence very much, so far as known, the amount of water which falls. It is claimed by some that the precipitation is greater in the forest than on unforested land, and the figures given in the table at the beginning of this paper seem to indicate a tendency toward lessened precipitation on those watersheds which will presently be shown as having a decreased forest area. However, it is not intended at present to lay any stress upon that point. If the influence of the various factors which affect stream flow have been correctly stated, none of them is sufficient to have caused the increased floods. The natural conclusion is that the increase must be due to changes in the ground cover, or to the ground cover in conjunction with changes in the soil. Is the influence of the ground cover and of the soil sufficient to have caused the results?

It is generally agreed by those who have studied the subject most thoroughly that the forest offers the best conditions for absorption and underground storage. Next to the forest comes well-cultivated farm land; then meadow and pasture land; while the worst conditions of all are to be found on barren surfaces of stone, clay, or gravel, which because of infertility are unable to support growth of any kind.

The reasons why the forest offers the best conditions for absorption and ground storage are several. It does so, in the first place, because the foliage of the trees forms a storage place from which water drips slowly to the ground for a considerable length of time after each rain; because the complex layer of brush, leaves, weeds, mosses, and vines, all in a more or less advanced stage of decay, becomes filled with moisture with each heavy rain and holds it for a considerable time; because, also, the surplus water so stored continues to be absorbed by the upper humus-filled layers of earth; because, further, the temperature is lower and the air more humid in the forest than in the open; finally, because the snow lies there much longer. To these reasons must be added the mechanical power of the roots to go deep into the soil and break up the rocks, thus forming channels for the ready entrance of water into the earth.

On a level or slightly inclined surface a well-tilled soil may be as effective in absorbing and holding water as a forest soil. Where the slope exceeds 10 per cent, cultivation does not long go on before erosion sets in, and erosion if unchecked will remove the soil and gully the surface until all fertility has gone and all protective power is lost. Agriculture under right conditions may be an effective means of stream protection; under wrong conditions it may be the greatest menace to the even flow and usefulness of the streams.

THE PRINCIPAL CAUSES OF INCREASED FLOODS.

Undoubtedly it is the clearing away of the forest on the mountainous watersheds of the streams which have been described that has caused the great increase in frequency and duration of floods.

It is a known fact that the forests on these several watersheds have been cut away with great rapidity during the past thirty years. European conditions probably offer no parallel to the rate at which these watersheds have been cleared to make way for the rapid advance of agriculture and to supply the great manufacturing industries with the wood which they require. Forest lands, which offer the best possible conditions for soil absorption and underground storage, those great regulators of stream flow, have been changed to poorly tilled agricultural lands, which are not so good. Then these agricultural lands after a few years have been exhausted and their soil eroded into deep gullies. Finally, many of them have been turned into pasture or even entirely abandoned because they reached a condition where they could not support even a growth of grass and weeds. The best condition has been changed to the very worst condition.

Again, repeated burning of forest lands has tended to reduce the thickness and value of the ground cover and to lessen the power of the soil to absorb and to store water. The extent of damage from fire, so far as water storage is concerned, is generally vastly underestimated. A forest fire strikes both above and below the surface. It injures or kills the trees, destroys the undergrowth and brush, and consumes the great forest sponge—the ground cover and the humus. The extent of the injury is, of course, not always the same. It is sometimes slight; sometimes very great. Repeated fires tend to every kind of injury that can possibly be inflicted upon a forest soil, completely destroying the cover down to the mineral substances, and thus rendering it defenseless against the attacks of erosion. When that stage is reached, it may be depended upon that the run-off of the watershed has been profoundly affected, and the regimen of the stream materially changed. The fact that forest fires have repeatedly swept over the watersheds of the streams under consideration makes it easy to believe that this factor combined with the clearing away of the forest for agricultural purposes has been the chief cause of the intensified flood conditions which the records now disclose.

THE VITAL PART OF A WATERSHED.

Considering the streams which drain the mountain regions, the most vital parts of the watersheds are the highest parts. It is there that precipitation is the heaviest, slopes the steepest, and the whole sum of conditions most influential. Therefore, so far as stream flow is concerned, the mountains are the portion which should be given the most judicious care. It is on the mountains that the best condition of soil and ground cover should be maintained. As the best ground cover, as has already been explained, is the forest, it is to the benefit of the streams that the mountains should be kept densely forested, in order that the conditions for the absorption and retention of moisture may be as nearly as possible ideal. Under such conditions the course of the moisture will be one of continual interference from the time it reaches the crowns of the trees till it is in the stream.

Every obstruction that can be placed in the way of the water aids by that much the even flow of the rivers. Under perfect forest conditions it is well-nigh impossible for any surface run-off to take place. The rain first comes into contact with the crowns of the trees, and the drops are broken more or less into spray. Some of the intercepted water runs down the trunks or drips from the branches. That which escapes interception by the trees encounters the undergrowth and brush immediately above the ground and is intercepted and retarded. As the water continues to make its way downward the ground litter offers the next obstacle. The water is caught up by the litter, and not until this has become saturated can the water pass on. If the rain continues for some time the litter becomes filled to its capacity, and then the humus begins to absorb the water which the litter can not hold. After a time it, too, becomes saturated. The water then gradually filters into and through the underlying soil. If this is deep it stores water in large quantity and then allows the surplus to pass to still greater depths, where it finally penetrates the rock strata and replenishes the great underground reservoir, from which it emerges later as springs, some of which may be far removed, even on the opposite side of the mountain, from the place where it has come in contact with the ground. If the precipitation is in the form of snow its course is substantially the same, but with a still greater delay in passing through the litter and entering the soil. The period that may elapse between the fall of rain and the appearance of water in a river varies from minutes to months or even years.

Even with the best regulated system of checking and storing the rainfall a condition may arise where, to a large extent, the effect of obstruction and storage in a forest may temporarily be lost. Severe and prolonged freezing may result in a sheet of ice in and over the upper soil, which prevents the entrance of water, and whatever falls in the form of rain must at once run off into the streams. Many rivers experience their worst floods when their drainage basins are frozen. On account of this condition is is impossible to claim that extreme floods will not come in a stream with a forested watershed. Fortunately the condition arises but seldom.

In such cases the conditions are similar to what they would be were the covering of the soil removed. The disastrous floods which come once or twice in a generation when heavy rains descend upon snow and frozen ground would probably be duplicated or surpassed yearly, or several times a year, were the soil stripped from the mountain regions. The heavy rains of summer which now fall upon a dense vegetation and hardly affect the larger rivers would then produce destructive floods.

A COMPARATIVE STUDY OF WATERSHED CONDITIONS.

The table on a preceding page gives data regarding the flow of 10 important rivers of the United States. It has not been possible to obtain for each watershed a record of the changes which are believed to be responsible for the increased flood conditions which the record shows. It has been possible to make a detailed study of parts of the watersheds of two of the streams, the Cumberland and the Red.

A WATERSHED WHERE CONDITIONS HAVE GROWN WORSE.

The Cumberland River is a good example of how conditions have changed for the worse on some of these watersheds.

The drainage area of the Cumberland River above Burnside, Ky., comprises 3,739 square miles and lies in the heart of the Cumberland Mountains. The figures given in the table show that floods have increased in the Cumberland River at Burnside, Ky., in number from 32 in the first half to 43 in the second half, and in duration from 89 days in the first half to 102 days in the second half, while low waters have increased in times from 61 in the first half to 65 in the second half, and in days from 1,261 in the first half to 1,576 in the second half.

The removal of the forest on this watershed is progressing from three causes: (1) Clearing for agriculture; (2) lumber operations; (3) fires.

In 1890, when these measurements were begun, 21 per cent of the watershed above Burnside was cleared; in 1908 the cleared area had grown to 32 per cent. During the eight years from 1900 to 1908 clearing of forest for agricultural purposes went on on this watershed at the average rate of five-eighths of 1 per cent per year.

The total stand of timber on this part of the Cumberland watershed is 6,212,531,000 board feet. It is being cut away by lumbering alone at the rate of 4 per cent a year. These figures show that timber is disappearing on account of lumber operations eight times as fast as it is removed to clear land for farming purposes. In other words, supposing that lumbermen would cut clear as they go, 8 acres would be stripped for timber to 1 cleared for agriculture. The forest is not being cut clear. Instead, the lumberman is going over it time after time, picking out the particular kinds or classes of timber that he wants. First, he took the walnut and cherry; next, the white oak and poplar; now he is taking the chestnut and other kinds of oak. At the present time few tracts can be found from which one or more of the valuable timbers have not been culled. Other tracts have been stripped of nearly their entire growth.

At intervals of from one to five or six years fires run through the woods on the hills and mountains where the Cumberland River has its source. The fires are more frequent and destructive in districts where part of the timber has been cut and the refuse left on the ground. The dry ridges burn oftener than the coves, because the latter are sometimes too damp for burning. In times of prolonged drought, however, fires run through the ravines and coves where the densest growth is found. The fires are usually slow, and the damage to mature timber is not great, but the injury to the young growth is frequently excessive, and soil damage is serious. As a rule all seedlings and sprouts less than 4 or 5 feet high are killed, and, since fires come at intervals so frequent that the young growth can not attain a size above that, a large part of what would be the future forest, as well as the present ground cover, is destroyed. The surviving stand thus becomes thinner year by year, since it can not be replenished by young growth, and since the mature trees are steadily falling by natural decay or by the ax.

Though the fires are slow and small, they burn the leaf cover and the upper layers of humus at each visitation. This removes or injures the porous surface, one of whose essential functions is to arrest the storm water falling upon the slopes and afford it an opportunity to sink into the ground. With the packing of the surface, after the litter and humus have been burned away, the water flows down the slopes and quickly reaches the streams, where, if in sufficient quantity, it produces flood conditions. Low water follows, because the hard ground is able to take in but little of the storm water to be paid out slowly afterward.[a]

The behavior of the Cumberland River shows a direct and positive relation between the run-off and the changed condition of the surface. The changes due to agriculture and lumbering can be definitely stated, but the extent and effect of forest fires are not subject to exact calculation. Yet undoubtedly all of these influences are active in producing the results as shown in the flood and low water records at Burnside. It is impossible that these results should be due to rainfall, because the rainfall was approximately 10 per cent less in the second half of the period. Since no other influences could have produced the result, there is no conclusion possible other than that the progressive floods and low waters have been due to the changes accomplished on the surface of the watershed.

A WATERSHED WHERE CONDITIONS HAVE GROWN BETTER.

The fact that man by his operations may decidedly change the regimen of a river is shown not alone by those streams whose flow has been influenced by clearing away the forest. It is shown, on the other hand, by streams whose watersheds of prairie soil compacted for ages by the trampling of buffalo, and more recently by cattle of the great ranches of the West, have been to a large extent brought under cultivation.

A stream which shows this tendency in an unmistakable way is the Red River, which forms the boundary for many miles between Texas and Oklahoma. On this stream records of flow are available for sixteen years. The number of floods in the first half of this period was 19; in the second half, 16. The number of days of flood in the first half was 87; in the second half, 60. Considering also the low-water periods of this river, we find that in the first half of the period there were 49 periods of low water; in the second half there were 8. In the first half the duration of low water was 826 days; in the second half, 208 days. A falling off in the rainfall occurred on this watershed, there being 1.94 inches less water per year in the second than in the first. Its drainage basin is, and has been during the time of its known history, practically without forests, only 1 acre in 10 being forested. In that respect it differs from all eastern and many western rivers whose basins are more extensively forest covered.

---

[a] A more definite statement regarding the damage to humus by fire may be made for the upper watershed of the Potomac River. In Water-Supply Paper, No. 192, the U. S. Geological Survey shows that 838 square miles of the forest of this watershed had been so severely burned by repeated fires as to completely or almost completely destroy the humus. Other tracts aggregating twice that area had their soil severely damaged, but not to the point of complete destruction of the humus. Considered together, these burned-over lands have an area of over 2,500 square miles, or 27 per cent of the drainage basin above the point of measurement. Assuming that the humus of the uninjured forest soil of the Potomac basin would hold back for absorption 2 inches of water, and assuming that with the humus damaged as in this case the capacity of the soil for receiving water is lessened one-half, then 1 inch will be held instead of 2 inches, as formerly. In an area of 2,500 square miles, the inch of water, which formerly was absorbed but now flows away quickly, amounts to about 6,000,000,000 feet. During a heavy rain that quantity of water in excess of what would flow off quickly before would go at once to the streams.

The rating table for the Potomac at Point of Rocks, where the measurements were made, shows that when the river is at a 10-foot stage 61,000 cubic feet of water pass per second. The 6,000,000,000 cubic feet of extra flood water from the burnt forest is therefore sufficient, without a gallon from other parts of the basin, to maintain a 10-foot stage at Point of Rocks for thirty hours. The effect on succeeding low-water stages is a logical one. There is simply 6,000,000,000 cubic feet less of stored water to come gradually after the rains cease.

Why has the Red River constantly changed its flow toward steadiness and uniformity, while many other rivers have changed in exactly the opposite direction? The area of the Red River drainage basin above Arthur City, Tex., where the records were made, is 40,200 square miles, divided almost equally between Oklahoma and Texas. In this river, as in those before mentioned, the geology and topography have not changed. The precipitation has changed considerably in the direction of lessened rainfall, but not enough to account for the record. In soil conditions, and especially in the condition of the surface, however, the change has been marked. At the beginning of the period of measurement, in 1890, the country was for the most part occupied by large ranches. The native prairie sod had never been broken up.

On the part of the watershed lying in Texas there had been some settlement at an early date, but as late as 1900 no more than 12 per cent of the Texas part of the watershed had been improved. In the Oklahoma part of the basin, in the same year, the improved portion was 16 per cent. Development began most extensively about 1900. In southwestern Oklahoma, in that portion drained by the Red River, it was stimulated by the opening of Indian reservations to settlement. The Cheyenne, the Arapahoe, and the Wichita lands were opened, it is true, in 1890, but the real opening of the country to settlers came in 1901, when the Comanche, the Apache, and other Indian lands were opened, aggregating over 10,000 square miles, or more than one-fourth of the entire Red River basin above Arthur City. Another tract of over 8,000 square miles, the Choctaw and Chickasaw lands, began its development about the same time. A summary of these figures shows that in 1908 the Red River basin in Oklahoma had 10,200 square miles of improved land, instead of 3,284 square miles in 1900. Statistics are not complete for the Texas portion of this basin, but the Texas portion has developed at about the same rate as the Oklahoma part. It is probable that the whole Red River basin above Arthur City, in Texas and Oklahoma, had 40 per cent of its land under improvement in 1908, instead of 14 per cent eight years earlier.

The results which have appeared in the form of change of the flow in the Red River are precisely what ought to be expected from the changes in surface conditions. Theoretically, such results should appear, and as a matter of fact, they have appeared. The hardened prairie soil has been broken up and changed into cultivated fields over 40 per cent of the area, and thereby the absorptive capacity of the soil has been much increased. Over the remainder prairie fires have been kept out and better growth of grass secured. The extensions of cultivation and the improvement of the grass land has tended to equalize the flow of this river. The river's behavior has become better as the area of wild land has decreased. In other words, wild, barren land, being the worst condition for the protection of a watershed, and cultivated farm lands being next to forests the best condition, the change of a large part of the watershed from the worst condition to the next to the best condition has brought about this result.

The same law is thus seen to work on both the Cumberland and the Red River watersheds, but in different directions. On the Cumberland, as the watershed changes from the forest (the best condition for stream protection) to farm land, to pasture land, and even to barren condition (the very worst condition for absorption), the flow of the river is made more extreme, both as to floods and low waters. On the Red watershed, beginning with a wild, almost barren, compacted surface, cultivation has changed the condition to that of permeable farm lands, which, next to forests, offer the best conditions. These two extremes exemplify, therefore, in different directions, the working of the same law—that there is a vital relation between the condition of the surface of the watershed and the manner of flow of the stream which drains it.

DENUDATION.

By R. B. Dole and H. Stabler,
Water Resources Branch, United States Geological Survey.

INTRODUCTION.

The accompanying tables present estimates of the rate of denudation in the United States. The figures show the rate at which the earth's crust is being moved as solid particles carried in suspension by streams and as matter carried in aqueous solution. The first table is a summary of the estimated denudation for the whole United States and for the primary drainage basins; the other tables contain detailed estimates for smaller areas. The map indicates graphically the rates of denudation in different parts of the country.

SOURCES OF DATA.

The computations of denudation factors are based on figures representing the amount of mineral matter carried by streams, the size of the areas tributary to the streams, and the quantity of water discharged by the streams. The run-off data are derived principally from measurements made by the water-resources branch of the United States Geological Survey; some of the measurements, especially in lower Mississippi Valley and on the Great Lakes, were made by the Engineer Corps, U. S. Army; the Weather Bureau, Department of Agriculture, has contributed series of gage heights in several streams; and estimates of run-off based on the best available information have been made for areas regarding which no measurements are at hand. The estimates of the size of the drainage basins are either copied from printed reports or measured from the best available maps. The greater part of the chemical data are derived from complete mineral analyses of river waters, about 5,000 in all, performed for the water-resources branch under the direction of R. B. Dole by W. M. Barr, F. W. Bushong, C. K. Calvert, W. D. Collins, F. M. Eaton, J. R. Evans, P. L. McCreary, Chase Palmer, J. L. Porter, M. G. Roberts, F. C. Robinson, Walton Van Winkle, and A. J. Weith. Daily samples of water were collected for one year from about 150 rivers and lakes in California and in the States east of the one hundredth meridian. Ten consecutive samples were then united and the composites thus obtained were subjected to complete mineral analysis. The information regarding dissolved and suspended matter in the streams of the arid States, except California, has been furnished by the United States Reclamation Service from work

ANDREW B. GRAHAM CO.

RATES OF DENUDATION IN THE UNITED STATES
The figures are the number of years required for one inch of denudation.

Senate Doc. No. 676; 60th Cong., 2d. Sess.

done under the direction of W. H. Heileman, but unfortunately the detailed analyses could not be procured and therefore the comparative accuracy of the estimates is unknown. In the California and the Reclamation Service work 50 cubic centimeters of filtered and 50 cubic centimeters of unfiltered sample were evaporated, dried at 110° C., and weighed to determine suspended and dissolved solids. In the other analyses the suspended matter in 500 cubic centimeters of the sample was removed by filtration through a Gooch crucible, dried at 180° C., and weighed for suspended solids; the filtrate was then evaporated, dried at 180° C., and weighed for dissolved solids. Some error is introduced by comparing solids determined at 180° with solids determined at 110°. The size of the error varies with the amount of organic matter and water of crystallization present and with the character of the solids themselves, and is probably variable for different rivers and for the same river from time to time; consequently no correction for it has been made. In most cases, however, this circumstance introduces less than 10 per cent error.

The figures for Kennebec River are computed from analyses by G. C. Whipple and E. C. Levy. The dissolved solids for Connecticut River and for Housatonic River are from reports of the Connecticut state board of health; for Merrimac River, from reports of the Massachusetts state board of health; for Blackstone River, from reports of the Rhode Island state board of health. The data for Hudson River at Albany, N. Y.; Potomac River at Great Falls, Md.; and Allegheny River at Pittsburg, Pa., are from reports of water-supply investigations at those places. The figures for Colorado River at Yuma, Ariz., are computed from analyses by R. H. Forbes and from others made in continuation of his work by the Reclamation Service. The data for Ohio River at Louisville, Ky., and at Cincinnati, Ohio, are quoted from reports by G. W. Fuller. The data at West Alton and at Jefferson Barracks, Mo., are quoted from analyses by A. W. Palmer in connection with the case of the State of Missouri against the State of Illinois and the sanitary district of Chicago. The estimates of suspended and dissolved solids at New Orleans, La., are computed from fifteen years' sediment determinations by the Engineer Corps, U. S. Army, and from five years' determinations by the New Orleans water and sewerage board. In all the quoted analyses the estimates are given by weight and not by volume, and in nearly all cases they show the average condition of the water for one or more years.

METHODS OF COMPUTATION.

The estimates of denudation, computed from the above-mentioned data by H. Stabler, indicate the removal in solution and suspension of solids from the primary and secondary drainage basins of the United States as classified by the Geological Survey. The determinations on which the computations are based are given in detail. The eleven primary basins are designated by Roman numerals. Under the secondary basins, which are designated by Arabic figures, important tributaries and the sampling stations are indicated.

The second, third, fourth, and fifth columns of the tables give, respectively, the areas of the basins, the dissolved solids, the suspended solids, and the annual run-off per square mile. In columns 6 and 7 the annual denudation in tons per square mile for the areas above the points at which samples were collected is computed by multiplying together solids in parts per 1,000,000, run-off in second-feet per square mile, and 0.985; in all other regions the denudation is estimated from the data for known areas. Columns 8 and 9 show the total denudation in thousands of tons per year, computed for the secondary areas by multiplying denudation in tons per square mile per year by the drainage area in thousands of square miles.

The depth in millionths of an inch per year covered by the material removed is found by dividing the tons per square mile per year by 0.1917 and the last three columns bear reciprocal relations to columns 10, 11, and their sum. Any attempt to estimate erosion in volumetric terms from determinations of dry suspended matter and dissolved solids involves the use of factors which are by no means absolute. The actual specific gravity of the mineral substance carried in streams in the United States is not greatly different from 2.6. This figure is practically identical with that commonly assumed for the specific gravity of the earth's crust and corresponds to a weight of 165 pounds per cubic foot. Each 165 pounds of substance found in water, therefore, represents the erosion of approximately 1 cubic foot of the crust of the earth, and estimates of ultimate rock losses based upon these figures are probably not in error more than 8 or 10 per cent. Common earth or loam, however, contains a large amount of air space, or voids, and dry earth is estimated as weighing 80 to 110 pounds per cubic foot. If an estimate of erosion be made upon this basis the error for a large area will probably not be great, but may amount to 20 per cent or more when calculations are made for small areas. Finally a third factor for calculation is based upon an attempt to determine the volume of river sediment or mud banks that a given weight of suspended matter may form. Investigators working upon different streams in the United States have obtained results indicating that a cubic foot of sediment may be produced by 50 to 125 pounds of dry material. The compactness of the mud is so variable that an estimate of this nature based upon an average of 90 pounds per cubic foot is likely to be in error by about 45 per cent. In view of the widely divergent values given for river sediment and for surface loam, the estimates for denudation expressed in millionths of an inch in depth from the entire drainage area and in years required for the erosion of 1 inch from the drainage area are based upon the assumption that 165 pounds of suspended or dissolved solids represent the removal of 1 cubic foot of the earth's crust. The factor 0.1917 has been computed on that basis. For the convenience of those who prefer a different basis of calculation, the following table of ratios is presented. The figures given in this report for denudation in inches can be recomputed by dividing them by the ratio corresponding to the weight given in column 1.

Ratios for recomputing denudation in inches.

Weight of material per cubic foot.	Corresponding specific gravity.	Ratio.
Pounds.		
165	2.64	1.00
150	2.40	.91
140	2.24	.85
130	2.08	.79
120	1.92	.73
110	1.76	.67
100	1.60	.61
90	1.44	.55
80	1.28	.49
70	1.12	.42
60	.96	.36
50	.80	.30

The estimates for the primary basins and for the whole United States are based upon the estimates for the secondary areas.

PROBABLE ACCURACY.

The majority of the figures for run-off per square mile per year are based upon discharge measurements extending over periods of seven years or more and are, with a few exceptions, within 10 per cent of the true average values. The drainage areas in square miles are so nearly correct that their errors are negligible in these calculations. The estimates of dissolved solids represent the average condition of the water for a period of one year or more. By comparison of annual averages for several streams in different years it has been estimated that the average for one year is generally not over 10 per cent from the correct average value, and it is undoubtedly true that the average total solids does not vary from year to year nearly so much as the average run-off. On the other hand, suspended solids are subject to greater variation than run-off. Floods are always attended by extreme rises in suspended solids, and the amount of suspended matter is subject to enormous variation from place to place on account of changes in stream velocity, the character of the river bed, and other features. In consequence of these facts, it is possible that denudation estimates, based on average suspended matter for one year, may be in error as much as 50 per cent. When all these facts are considered in conjunction with the distance of the sampling stations from the mouths of the rivers, it may be estimated that the calculated figures for denudation are generally within 20 per cent of the true values. Only two significant figures, therefore, have been retained in the last five columns. In many streams of the arid and semiarid regions the yearly fluctuations in run-off are very great and the mineralization of the waters is very high, so that estimates of denudation in that part of the country are not so reliable as similar estimates for eastern rivers. As the analytical data for the northern Pacific, Hudson Bay, and western Gulf of Mexico basins are extremely meager, the estimated denudations for those areas may be more than 20 per cent in error, and further investigations in those regions must be made before reliable values can be calculated.

DISCUSSION OF SUMMARY.

The summary presents in tabular form denudation estimates for the primary drainage basins and for the whole United States. The figures for dissolved solids practically represent material carried into the ocean; the figures for suspended solids, on the other hand, represent more properly material carried to tide water, because the decrease in stream velocity at that point occasions a gradual deposition of the matter transported in solid form. The tons per square mile per year removed from different basins show interesting comparisons. In respect to dissolved matter, the southern Pacific basin heads the list with 177 tons, the northern Atlantic basin being next with 130 tons. The rate for Hudson Bay basin, 28 tons, is lowest; that for the Colorado and western Gulf of Mexico basins is somewhat higher. The denudation estimates for the southern Atlantic basin correspond very closely to those for the entire United States. The amounts are generally lowest for streams in the arid and semiarid regions, because large areas there contribute little or nothing to the run-off. The southern Pacific basin is an important exception to this general rule, presumably because of the extensive practice of irrigation in that area. The amounts are highest in regions of high rainfall, though usually the waters in those sections are not so highly mineralized as the waters of streams in arid regions.

Colorado River brings down the most suspended matter, delivering 387 tons per year for each square mile of its drainage basin. Though many small streams bring silt into the Great Lakes, sedimentation clears the water, and practically no suspended matter is transported by St. Lawrence River. In general much less suspended matter is carried by northern than by southern rivers, a phenomenon influenced probably more by the texture of the soil and the subsoil and the geologic character of the rocks than by stream velocity.

The detailed estimates throw considerable light upon the progress of erosion in different sections of the river valleys. The Mississippi, for instance, apparently discharges more material than is brought in by its tributaries, thus indicating that its lower valley is still being eroded. The lower Colorado, however, appears to be receiving deposits from both dissolved and suspended matter taken from its upland drainage area. The Rio Grande is similar to the Colorado in this respect.

The estimates reveal that the surface of the United States is being removed at the rate of thirteen ten-thousandths of an inch per year, or 1 inch in 760 years. Though this amount seems trivial when spread over the surface of the country, it becomes stupendous when considered as a total, for over 270,000,000 tons of dissolved matter and 513,000,000 tons of suspended matter are transported to tide water every year by the streams of the United States. This total of 783,000,000 tons represents more than 350,000,000 cubic yards of rock substance, or 610,000,000 cubic yards of surface soil. If this erosive action had been concentrated upon the Isthmus of Panama at the time of American occupation, it would have excavated the prism for an 85-foot level canal in about seventy-three days.

Summary.

Drainage basin.	Physical and chemical data.				Estimated denudation.								
	Area (square miles).	Solids (parts per million).		Run-off (second-feet per square mile).	Tons of solids per square mile per year.		Thousand tons of solids per year.		Millionths of an inch per year.		Years required for 1 inch.

DEVELOPED WATER POWERS.

Compiled by the Bureau of the Census, under the direction of W. M. STEUART, Chief Statistician for Manufactures.

Discussion by M. O. LEIGHTON, Chief Hydrographer, U. S. Geological Survey.

A special census of the developed water powers of the United States has been made by the Bureau of the Census for the specific purposes of the conservation report. Previous inquiries of the same kind, made by this bureau, afforded a record of the names and locations of practically all the water-power developments that had taken place up to the dates thereof, and this record was used as the basis for the new census. Information concerning the developments that have been made since the date of the last census was procured through the Geological Survey, Forest Service, Bureau of Corporations, Post-Office Department, and many other agencies, both state and national. Special inquiry blanks were sent to all, including those that had figured in past censuses.

In making the new census it was necessary to procure the data in large measure by mail, and therefore it was necessary to simplify the inquiry and to secure only the facts absolutely necessary to a comprehensive summary of the developed water powers. The inquiry blank used for this purpose is reproduced below:

[Return this card to the Department of Commerce and Labor, Bureau of the Census, Washington, D. C.]

WATER POWER, 1908.

This office is engaged in the preparation of a report on the developed and undeveloped water power of the United States. If you use water power, please answer the following inquiries. If you do not use water power, please so state, and give the names and addresses of any power plants in your neighborhood. The card should be returned in the inclosed official envelope.

Name ------------------------------
Post-office ---------------------- State ----------
Location of plant: County ---------------- State ----------
Name of river or stream on which plant is located ----------
Number of water wheels ---------- Maximum horsepower ----------
Horsepower actually developed during low-water season ----------
Additional power that may be developed at same point on the same river or stream, horsepower ----------
Auxiliary steam power used in same plant, horsepower ----------
Character of industry ------------------------------
(Give name of principal product.)
Give names and addresses of other power plants in your neighborhood ----------

The character of the returns and the proportion of replies received indicate that the census is fairly complete. It is known that a greater number of the plants not accounted for in this census are of small capacity. There is, of course, some deficiency in the total; but it is believed that this is compensated by the general tendency among water-power owners to return statements based on actual wheel capacity installed rather than actual minimum power developed during the extreme low-water season. In all wheel installation it is the practice to develop above the minimum flow, and it follows that in the majority of power plants there must be a tendency to overstate the power actually developed during the lowest water. The final figures represent what is believed by those most conversant with the situation to be a reasonably accurate summary of the water power now developed in the country.

The material procured from the census has been arranged by drainage areas and combined into grand divisions, according to the plan followed in the report on undeveloped water power.

Accompanying Table No. 1 gives a general summary of the horsepower developed in the United States and the number of wheels used for such development. It will be noted that this table gives results according to States as well as according to grand divisions.

Some interesting facts are shown. The total development in the country is 5,356,680 horsepower over 52,827 wheels, or an average development per wheel of about 100 horsepower. In the Northern Atlantic division there has been a greater water-power development than in any other, the total installation being 1,746,303 horsepower. The only other division that approaches the Northern Atlantic in development is that covering the drainage area of the St. Lawrence, including the Great Lakes, where there has been a development of 1,018,283 horsepower. The great power development in the Northern Atlantic division may largely be explained by the fact that the use of water power therein began at an earlier period than in any other divison. New England and the Middle Atlantic States are and have been essentially manufacturing in character, and water-power development has followed as a matter of course. It is also true that the presence of good powers in large numbers in this region has encouraged such development.

Comparisons of wheel capacities installed in various parts of the country are interesting. While the total figures show that the average power per wheel is 100 horsepower, the units in the various districts vary as follows:

Division.	Unit capacity horsepower per wheel.	Division.	Unit capacity horsepower per wheel.
Northern Atlantic	80	St. Lawrence	14
Southern Atlantic	77	Colorado River	[illegible]
Eastern Gulf of Mexico	42	Southern Pacific	[illegible]
Western Gulf of Mexico	47	Northern Pacific	[illegible]
Eastern Mississippi	60	Interior drainage	[illegible]
Western Mississippi	139	Arctic Ocean	[illegible]

The large number and small unit capacity of wheels in the eastern part of the country compared with the smaller number and larger capacity in the western portions, including, especially, the rivers draining from the Rocky Mountains and the Sierras, may be explained: First, by the fact that in the eastern and central portions of the country the power privileges are of smaller capacity; and second, by the fact that in the eastern portions of the country a large number of the powers were installed at an early date, when it was the rule to establish small units. More recent practice has involved the establishment of larger units, and as the western installations are all recent, this practice, taken together with the existence of larger power privileges, gives the result that might be expected from a general survey of the situation.

Table 1 shows that New York State has the largest water-power development, the total being 885,862 horsepower. It is proper to add that the Niagara powers on the New York side assist largely in making up this figure. The second State in water-power development is California, the total being 466,774 horsepower, over 1,070 wheels, or a unit installation of about 436 horsepower. Water-power development in California is comparatively recent. The third State is Maine, with 343,096 horsepower, over 2,797 wheels, or an average of 123 horsepower per wheel. As the use of water power in this State is comparatively ancient, the contrast in unit capacity between it and California is significant.

Among the other interesting points is the fact that, although, as shown by the report on undeveloped water power, the Northern Pacific division can be made to furnish about one-third of the total minimum horsepower of the country, there is at the present time a development of only 450,000 horsepower, which indicates clearly that the most fertile field for power development remaining in the United States is this northwestern country.

Table 2 gives the installations by districts and drainage areas, special comment concerning which is unnecessary.

Census returns show that, out of a total of 31,537 powers reported, 602 are of capacity of 1,000 horsepower or more. Recent progress in water-power development has been marked by great installations. In former years the aggregate water power utilized in the country was made up largely of small units, which, while useful for local purposes and worthy of development, are not relatively important in the great question of power economics. The following summary gives the distribution of the powers of 1,000 horsepower and greater capacity, and it shows clearly that what was formerly believed to be an uncommonly great installation must now be considered a comparatively small feature.

Capacity distribution of powers of 1,000 horsepower and more.

1,000 to 5,000	459
5,000 to 10,000	65
10,000 to 15,000	27
15,000 to 20,000	13
20,000 to 25,000	17
25,000 to 40,000	11
40,000 to 60,000	4
60,000 to 100,000	3
100,000 and over	3
Total	602

Number of water powers by States and Territories, 1908.

UNDEVELOPED WATER POWERS.

By M. O. Leighton,
Chief Hydrographer, United States Geological Survey.

The surveys and examinations necessary to a thorough and accurate report of the water-power resources of the United States have never been completed. In certain parts of the country the facts are sufficiently well known to make it possible to present a tolerably accurate statement. In other parts the information is fragmentary, and therefore power estimates must be considered approximate. Taken as a whole, however, the schedule here appended will be sufficient for the purposes for which it was prepared.

In order to present the information in a systematic way, the drainage areas of the United States have been united into groups according to geographic distribution. These group boundaries have been arbitrarily determined according to what seems to be the most convenient arrangement for the purposes of this report. The grouping is as follows: Atlantic Ocean, Pacific Ocean, Arctic Ocean, and interior drainage. These groups have been subdivided into 12 principal divisions, as follows: I. Northern Atlantic; II. Southern Atlantic; III. Eastern Gulf of Mexico; IV. Western Gulf of Mexico; V. Mississippi River (tributaries from the east); VI. Mississippi River (tributaries from the west); VII. St. Lawrence; VIII. Colorado River; IX. Southern Pacific; X. Northern Pacific; XI. Great Basin; XII. Hudson Bay.

SOURCES OF DATA.

The data used in this report have been obtained from the following sources:

The records of flow are mainly from the reports and files of the water-resources branch of the United States Geological Survey. As the period over which these records extend varies in length, a seven-year period, extending from 1900 to 1906, inclusive, was taken as a basis and all values of flow are the mean for these years.

The profiles and elevations have been obtained as follows:

(*a*) River surveys made by the United States Geological Survey, U. S. Army Engineer Corps, and others.

(*b*) Elevations as given by railroad and other levels.

(*c*) Dictionary of Altitudes, Bulletin No. 274, United States Geological Survey.

(*d*) United States Geological Survey topographic maps.

(*e*) Miscellaneous maps and reports of various State and other organizations.

In the use of maps the following preferences have been given: (1) United States Geological Survey topographic sheets; (2) special detailed surveys; (3) General Land Office maps; (4) United States post-route maps; (5) Rand & McNally Atlas sheets

WATER POWER.

The schedule presented in this report gives the amount of available water power according to three classifications—(1) that which may be produced by the minimum flow; (2) the assumed maximum development; and (3) the additional power that may be recovered by developing the available storage capacity in the upland basins and using stored water to compensate the low-water periods. The data as a whole have been considered without reference to present practicability of development or present market. For the purposes of this report it has been assumed that all the power in the United States will some day be required. Such an interpretation is the logical one when natural resources are being considered. In other words, the schedule here presented must be interpreted for the future rather than for the present. The reader should not assume that all the power here shown is economically available to-day. Much of it, indeed, would be too costly in development to render it of commercial importance under the present conditions of market and the price of fuel power. The schedule shows therefore what will be the maximum possibilities in the day when our fuel shall have become so exhausted that the price thereof for production of power is prohibitive, and the people of the country shall be driven to the use of all the water power that can reasonably be produced by the streams.

Consideration has been given to all the conditions that determine the possibilities of power production on the various rivers of the country. Especially has the slope of the stream channels been scrutinized. Theoretically, of course, the energy developed by the various rivers is that produced by the total fall of the water from source to mouth, but it has not been assumed that, even under ideal conditions of market, all this power will ever be commercially available. The flatter portions of the river channels can never be profitably developed for power and they have not been included in the schedule. The rivers have been divided into sections of varying length, determined by channel slope, and the fall and flow of each section have been obtained from the best available sources of information. The records of stream flow collected by the water-resources branch of the Geological Survey have almost uniformly been the only available resort, although acknowledgments should be made to the state water-supply commissions of New York and Pennsylvania; the state engineers of New York, Colorado, California, Oregon, and Nebraska; the territorial engineer of New Mexico; the state geological surveys of Maine, New Jersey, North Carolina, Virginia, Georgia, and Wisconsin; and various other bodies and individuals, public and private, who in the past have maintained measurements in cooperation with the United States Geological Survey or independently. Use has also been made of certain river gage records of the United States Weather Bureau and of the Corps of Engineers, U. S. Army.

In determining the flow for the various sections the data of flow per square mile, procured from the sources above enumerated, have been applied. The drainage areas above the upper and the lower limits of each section have been determined and a mean taken for the whole section. This has been used as a factor along with the flow per square mile in determining the minimum flow for that section. This figure, together with 90 per cent of the total fall from head to foot, has been used to determine theoretical horsepowers, according to the usual formulas. It is obvious that in practice the entire fall along any stretch of river or at any power privilege can not be effectively utilized. In few places can even 90 per cent be utilized at the present time; but, inasmuch as these figures are supposed to cover future as well as present practice, and inasmuch as it may reasonably be assumed that future practice in water-power installation will improve, it is believed that 90 per cent of the fall along any particular power privilege or section may eventually be realized.

The results of calculations of theoretical power on 90 per cent total fall have been reduced 10 per cent to allow for inefficiency of wheels. It is recognized that 90 per cent efficiency is too high to be used in calculations of power at the present time, 75 or 80 per cent being the usual installation maximum. Here again, however, we are computing for future conditions, as well as present ones, and it may confidently be expected that, with the improvement of turbines, a greater percentage of the theoretical power will be realized on the shaft and improvements will before long render possible a 90 per cent efficiency.

In determining the minimum horsepower, the minimum flow for the lowest two consecutive seven-day periods in each year was determined and the mean of these values for the period of record was taken as the minimum flow. It is obvious that this is somewhat higher than the absolute minimum, but the latter is usually of so short duration that it does not equal the practicable minimum that may profitably be installed.

The assumed maximum economical development has been determined on the assumption that it is good commercial practice to develop wheel installation up to that amount the continuance of which can be assured during six months of the year, on the assumption that the deficiency in power during the remainder of the year can be profitably provided by the installation of fuel power plants as auxiliaries. In many parts of the country it has been shown conclusively that it is economical to develop up to that amount which can be had continuously during the highest four months of the year, and, while it is probable that there are parts of the country where the limit should be the highest eight or ten months, it is believed that the period used in these schedules is a very conservative average. The minimum weekly flow for each month of the year has been arranged according to magnitude, and the sixth value has been taken as the basis for estimating the power, the mean of these values for the record period in each case being that used in the computations.

An endeavor has been made to determine the maximum power that might be produced if the practicable maximum storage available on the drainage areas were established. Surveys on many of the basins make possible a fairly close statement; but, inasmuch as fully three-fourths of the country has not been surveyed in a manner suitable for this purpose, only rough estimates can be given for the entire area. There are two methods by which an approximate estimate of total power can be made.

The first is to consider the power on those drainage areas for which suitable surveys are available and to increase the amount by the equivalent of the proportion left unsurveyed. An examination of the facts will show that the amount obtained by this method will be too low. It is apparent from a review of the index map showing the areas covered by such surveys that a fairly large proportion, probably one-third, comprises country in which good reservoir sites are either lacking or are uncommon in occurrence. Such portions include large parts of the Dakotas, Nebraska, Kansas, Oklahoma, Texas, and Louisiana, together with great areas on the Atlantic and Pacific coastal plains. Therefore to increase the total available water power from storage that may be computed on surveyed portions by the ratio of total surveyed portions to the entire country would hardly do justice to the situation. Nevertheless, the figures are here presented.

It is found that the total power available in the surveyed portions, including storage, is about 53,000,000 horsepower. If this be considered as one-fourth, to correspond with the portion of the country surveyed, the total power of the country, with practical maximum storage will be about 212,000,000 horsepower.

The second method of computation involves consideration of the increase of power available from storage in the several portions of the country in which surveys have been made, and applying the ratio of increase to unsurveyed and similar country in those regions. The topographic surveys, while they cover only one-fourth of the total area of the country, have nevertheless been prosecuted in all sections, so that the storage data are applicable to all physiographic types that are comprised within the United States. Applying the information in this way, we obtain a grand total of 230,800,000 horsepower, which, it appears to the writer, is a more accurate figure than that obtained by the first method.

In any case, therefore, it may be assumed with confidence that, were all practicable storage sites utilized and the water properly applied, there might be established eventually in the country a total power installation of at least 200,000,000 horsepower and probably much more.

In the actual management of storage for water power or for any other water utilization the stored waters are released according as needed, and they must be distributed according to the condition of the river and the length of the dry season. Therefore, water from storage is required for a varying number of months, according to the climatological conditions governing the river discharge. Some assumption in this matter has been necessary, and it is believed from the experience that has been gained in the study of rivers throughout the country that it will be fair and conservative to assume that, if any given storage be considered as released uniformly during six months of the year, and the natural flow from the unconserved areas be considered as sufficient to maintain at least an equal flow during the remaining six months, the results will not depart too widely from the actual conditions as regards total power that may be achieved in practice, unless, indeed, they are too conservative. It is well known that on some rivers an economical use of stored water would involve a shorter period of total release than six months to insure the most uniform distribution of discharge. This would provide for a greater power development than the six months of distribution. Nevertheless, the latter has been considered a fair average and has been used in the accompanying schedule.

Summing up the whole country according to the divisions thereof heretofore discussed, we obtain the general summary given below. Especial mention should be made of the fact that the results here given do not include the State of Pennsylvania, the figures for which had not been furnished up to the date of this report.

Estimate of stream flow and water power in the United States.

Principal drainages.	Drainage area in square miles.	Flow per annum in billion cubic feet.	Horsepower.	
			Minimum.	Assumed maximum development.
North Atlantic to Cape Henry, Va	159,879	8,942	1,712,050	[a]3,186,600

Northern Pacific	290,400	15,220	12,979,700	24,701,000
Great Basin	223,000	....	518,000	801,000
Hudson Bay	62,150	614	75,800	212,600
Total	3,269,490	72,672	36,916,250	66,518,500

[a] Not including area in Pennsylvania.
[b] Includes Rio Grande in Mexico.
[c] Includes drainage in Canada.

It will be noted from the foregoing that the region furnishing by far the greatest water-power possibilities is the northern Pacific, which comprises essentially the basins of Columbia and Sacramento rivers, the power possibilities there being about one-third those of the whole United States.

The following schedules give in detail figures concerning run-off and potential water power over the various drainage areas included within the several districts:

Estimate of stream flow and water power in the United States.

Total		62,150				614	75,800	212,600

---

[a] Values of drainage areas and discharge of the Great Lakes drainages derived chiefly from report of E. S. Wheeler, assistant engineer, U. S. Army. The discharge value is given for each of the Great Lakes as a unit from 1860 to 1892, and includes the run-off from both land and water surfaces. It shows the total discharge from both United States and Canadian territory.

[b] Includes Lake St. Clair.

[c] 3,500,000 horsepower at Niagara Falls on the basis of mean annual discharge.

[d] Includes Oswegatchie River and minor St. Lawrence tributaries above Ogdensburg, N. Y.

[e] Total horsepower of Niagara River and of tributaries to the Great Lakes in the United States.

[f] Southern Pacific included between Mexican line and Point Bonita, Cal.

[g] Exclusive of Tulare Lake drainage (see Sierra Nevada drainage).

[h] Includes Tulare Lake drainage.

[i] Northern Pacific included between Point Bonita, Cal., and Canadian line.

[j] Includes drainage area and flow in Canada, but does not include power.

[k] Does not include Tulare Lake drainage (see San Joaquin River).

[l] Includes drainage area and flow of Pembina and Mouse rivers in Canada, but does not include power.

[m] Drainage in United States only.

Estimate of stream flow and water power in the United States—Continued.

GENERAL SUMMARY.

Principal drainages.	Drainage area (square miles).	Flow per annum (billion cubic feet).	Minimum.	Assumed maximum development.
Northern Atlantic to Cape Henry, Va.	159,879	8,942		
Southern Atlantic to Cape Sable, Fla.	123,920	5,560	1,253,000	1,957,800
Eastern Gulf of Mexico to Mississippi River	142,220	6,867	550,000	963,000
Western Gulf of Mexico west of Vermilion River	[a] 433,700	[a] 2,232	433,760	822,650
Mississippi River (tributaries from east)	333,600	12,360		
Mississippi River (tributaries from west, including Vermilion River)	905,200	9,580	3,948,970	7,085,000
St. Lawrence River to Canadian line	[b] 299,720	[b] 8,583	6,682,480	8,090,060
Colorado River above Yuma, Ariz.	225,000	521	2,918,500	5,546,000
Southern Pacific to Point Bonita, Cal.	70,700	2,193	3,215,400	7,808,300
Northern Pacific	290,400	15,220	12,979,700	24,701,000
Great Basin	223,000		518,000	801,000
Hudson Bay	62,150	614	75,800	212,600
Total	3,269,489	72,672		

[a] Includes Rio Grande in Mexico.

[b] Includes drainage in Canada.

CONCENTRATION OF OWNERSHIP OF WATER POWERS.

By HERBERT KNOX SMITH,
Commissioner of Corporations.

The water-power situation has been greatly changed by recent improvements in electric-power transmission. Two-hundred-mile transmission is now regarded as commercially possible even in the cheaper coal areas. A two-hundred-mile radius opens an area of 120,000 square miles for the marketing of power from a given power plant.

A strong movement toward concentrating the control of water powers has accompanied this change. A very significant fact is that this concentration has taken place practically in the last five years. The chief existing concentrations are as follows:

(1) *General Electric*—being those power companies controlled by or having direct personal connections with the General Electric Company or its subsidiary corporations.

(2) *Westinghouse*—being those similarly connected with the Westinghouse Electric and Manufacturing Company, the Westinghouse Machine Company, and other Westinghouse interests.

(3) *Other concentrations* of water power which can not at present be identified with either of the first two.

Inter-company relations are easily concealed. Strictly judicial proof of such community of interests is rarely obtainable, nor is it necessary for practical purposes. It is sufficient to give, as herein, the significant evidential facts, leaving the obvious deductions to be made therefrom.

Therefore the General Electric and the Westinghouse concentrations are classified in the following groups:

(*a*) Those where a control by one or the other of these parent companies, directly or through subsidiary corporations, is admitted.

(*b*) Those where such control is inferred from substantial evidence (hereinafter summarized) with reasonable conclusiveness.

(*c*) Those where such control is at least partially indicated, though not proven, by the available evidence.

This report does not by any means assume to be a complete survey even of the present conditions of concentration. There may be many further affiliations as yet undiscovered. It is compiled, with two exceptions, from such data as the Bureau of Corporations had collected up to January 14, 1909, in the course of an investigation not yet completed.

The exact relations, if any, between these two groups (General Electric and Westinghouse) can not now be stated. General Electric and Westinghouse patents have been pooled since 1896, and certain individuals are interested in both General Electric and Westinghouse power companies.

(1) GENERAL ELECTRIC.

The control of the General Electric Company is shown directly or through subsidiary corporations, or indicated by the appearance of the names of certain individuals unquestionably connected with the General Electric Company.

Such subsidiary corporations are:

United Electric Securities Company (Maine, 1890).

Electrical Securities Corporation (New York, 1904).

Electric Bond and Share Company (New York, 1905).

Such individuals most closely connected with General Electric Company water-power control are—

Sydney Z. Mitchell, vice-president and treasurer Electric Bond and Share Company (General Electric; see above), formerly with Stone & Webster, of Boston, to be mentioned later.

J. D. Mortimer, assistant secretary Electric Bond and Share Company (General Electric; see above) and director of American Gas and Electric Company.

C. N. Mason, vice-president Electrical Securities Corporation and of United Electric Securities Company (General Electric; see above).

H. L. Doherty, president American Gas and Electric Company, which in 1908 controlled at least 19 lighting and gas companies in various parts of the United States, and is, in turn, controlled by the Electric Bond and Share Company (General Electric; see above).

Other names which may be mentioned are—

C. A. Coffin, president General Electric Company.

A. W. Burchard, assistant to the president, General Electric Company, and director of American Gas and Electric Company (General Electric).

C. W. Wetmore, director of Electric Bond and Share Company.

Hinsdill Parsons, vice-president General Electric Company and director of Electric Bond and Share Company.

(*a*) Those water-power companies which are admittedly controlled by the General Electric Company or its subsidiary companies are—

Schenectady Power Company, New York, developments on the Hoosick River at Schaghticoke and Johnsonville, with a total development of 26,000 horsepower. This company is owned outright by the General Electric Company.

Carolina Power and Light Company, at Raleigh, N. C., with 4,000 horsepower installed on the Cape Fear River, and leasing power, in addition, on the Neuse River. The stock of this company is held by the Electric Bond and Share Company (General Electric) and voted by Mr. J. D. Mortimer. C. Elmer Smith, of Smith interests in Westinghouse group, is also interested.

Rockingham Power Company, in North Carolina, on the Yadkin River, in process of construction, with an installation to be of 32,000 horsepower. This company is financed by the Electrical Securities Corporation (General Electric), C. N. Mason of the latter being president. C. Elmer Smith (see above) is also interested.

Animas Power and Water Company, Colorado, on the Animas River, with 8,000 horsepower installed, is controlled through the Electric Bond and Share Company (General Electric).

Central Colorado Power Company, in Colorado, together with the Eastern Colorado Power Company, which it owns, has on the Grand

River and Middle Boulder Creek installations to be of 63,000 horsepower and power sites in addition amounting to at least 25,000 horsepower. This company is being financed by W. P. Bonbright & Co., of New York City; Lee, Higginson & Co., of Boston, and the Electric Bond and Share Company (General Electric). Mr. H. L. Higginson, of Lee, Higginson & Co., is a director of the General Electric Company. Mr. S. Z. Mitchell, of the Electric Bond and Share Company, is a vice-president and member of the executive committee of this power company.

(*b*) Those water-power companies, the control of which by the General Electric Company or its subsidiary companies is reasonably inferred, are—

Montgomery Light and Water Power Company, near Montgomery, Ala., on the Tallapoosa River, with an installation of 6,000 horsepower. H. L. Doherty, president, American Gas and Electric Company (General Electric), is first vice-president of this company.

The Summit County Power Company, at Dillon, Colo., with an installation of 1,600 horsepower, has Mr. H. L. Doherty, of American Gas and Electric Company (General Electric), on its directorate.

Butte Electric and Power Company (Montana), a holding company for various subsidiary power companies, to wit: Montana Power Transmission Company, Madison River Power Company, Billings and Eastern Montana Power Company. These companies comprise six water-power developments in operation, with a total installation of 43,000 horsepower. The holding company (Butte Electric) is apparently controlled jointly by C. W. Wetmore, of Electric Bond and Share Company (General Electric), and C. A. Coffin, president of General Electric Company. P. E. Bisland, secretary, was formerly with Electrical Securities Corporation (General Electric).

Washington Water Power Company has three developments in Washington and Idaho, on the Spokane River, with a total installation of 61,000 horsepower. Mr. Hinsdill Parsons, vice-president of General Electric Company and Electric Bond and Share Company (General Electric), is on the directorate.

Great Western Power Company, in California, on the north fork of the Feather River in Butte County, with an installed capacity of 53,000 horsepower. On its directorate are Mr. A. W. Burchard, of the General Electric Company, and Mr. A. C. Bedford, of the Standard Oil Company. Mr. Bedford is also president of the Portland General Electric Company (see below).

(*c*) Control partially indicated.

There are also a number of other water-power companies, with a total of about 420,000 horsepower (including installations and power sites), whose connection with the General Electric Company is at least partially indicated, though the evidence thereto is by no means conclusive.

(2) WESTINGHOUSE.

The Westinghouse group contains the following companies:

The Security Investment Company;

Electric Properties Company (New York, 1906), Westinghouse, Church, Kerr & Co., subsidiary of Electric Properties Company.

Smith interests, represented by C. Elmer Smith and S. Fahs Smith, of S. Morgan Smith Company, important manufacturers of water turbines. While C. Elmer Smith is interested in at least two General Electric power companies (Carolina and Rockingham; see above), the Smith interests seem especially harmonious with the Westinghouse group, and are so classified.

The individual names most prominently identified are:

John F. Wallace, of New York, president Electric Properties Company.

George C. Smith, of Pittsburg and New York, vice-president of the Security Investment Company and vice-president and director of the Electric Properties Company.

C. Elmer Smith, of Smith interests.

(*a*) Those power companies which are admittedly Westinghouse are:

Atlanta Water and Electric Power Company, on the Chattahoochee River above Atlanta, Ga., with an installation of 17,000 horsepower. C. Elmer Smith is president, and George C. Smith and S. Fahs Smith directors.

Ontario Power Company of Niagara Falls, a Canadian corporation on the Canadian side, with an installation of 66,000 horsepower. Together with its distributing company in the United States, the Niagara, Lockport, and Ontario Power Company, it is known as a Westinghouse concern, H. H. Westinghouse being president of the latter, and stock being held therein by the Security Investment Company (Westinghouse).

(*b*) Those power companies whose connection with Westinghouse interests is inferred from substantial evidence are:

Albany Power and Manufacturing Company, near Albany, Ga., with 3,500 horsepower installed, on the Kinchatoonee, and owning beside a site on the Flint River, estimated at 10,000 horsepower, has for its vice-president C. Elmer Smith (Smith interests).

Electric Manufacturing and Power Company, on the Broad River, near Spartanburg, S. C., with 11,000 horsepower installed, has on its directorate E. H. Jennings, of Pittsburg, a director of the Electric Properties Company (Westinghouse).

Savannah River Power Company, on the Savannah River, near Anderson, S. C., has an installed development of 3,000 horsepower, and owns besides a site of 6,000 horsepower. This company has on its directorate C. Elmer Smith (Smith interests).

Gainesville Electric Railway Company, with 1,500 horsepower installed, on the Chestagee River, a tributary of the Chattahoochee, near Gainesville, Ga. Eighty-five per cent of its stock is owned by the North Georgia Electric Company (Smith interests).

North Georgia Electric Company; one development of 3,000 horsepower and at least seven other power sites on the upper waters of the Chattahoochee, and through the Etowah Power Company, personally identified with itself, it owns four other sites on the headwaters of the Coosa River. C. Elmer Smith is vice-president.

Chattanooga and Tennessee River Power Company, in process of construction at Hale Bar, on the Tennessee River, below Chattanooga, in cooperation with the War Department, by which the Government obtains slack-water navigation. The company in return receives ownership of the power of 58,000 horsepower to be installed. This company is being personally financed by A. N. Brady, of New York, a director of the Westinghouse Electric and Manufacturing Company. Mr. Brady is also a director of the American Tobacco Company, whose interests control the Southern Power Company (see below).

Northern Colorado Power Company, with a steam development at Lafayette, Colo., and reported as having acquired a water power site of 20,000 horsepower on South Platte River, has John F. Wallace and George C. Smith of the Electric Properties Company (Westinghouse) on its directorate.

(*c*) Control partially indicated.

There are also a number of other water-power companies, with a total of about 102,000 horsepower (including installations and sizes), whose connection with the Westinghouse Company is at least partially indicated, though the evidence thereto is by no means conclusive.

(3) OTHER CONCENTRATIONS.

The General Electric and Westinghouse companies present the most important examples of water-power concentration, as above set forth. There are, however, a number of other companies and interests further showing the facts and tendencies of concentration.

The more important instances are as follows:

The Gould interests located in Virginia, with undeveloped powers and power sites on the James and Appomattox amounting to 20,000 horsepower, and owning besides other sites on the Appomattox and Rappahannock rivers.

Southern Power Company, the largest operating power company in the South, has 90,000 horsepower installed in three developments, 31,000 horsepower in process of construction, and at least seven other power sites in North Carolina and South Carolina, with a total potential capacity of 75,000 horsepower. This company supplies 110 cotton mills and other factories in at least 28 towns, including a population of about 200,000. Messrs. B. N. Duke, J. B. Duke, and Junius Parker, of the American Tobacco Company, are officers and directors.

Stone & Webster, of Boston. This concern controls or manages powers and power sites in Florida, Georgia, Minnesota, and Wisconsin, and in the Puget Sound region, with a total capacity of about 150,000 horsepower. Mr. Sydney Z. Mitchell, now of the Electric Bond and Share Company (General Electric), was formerly connected with Stone & Webster, and in 1908, according to Moody's Manual, 1908, was still a director in three of Stone & Webster's managed corporations, to wit, Puget Sound Electric Railway, Tacoma Railway and Power Company, and Puget Sound Power Company.

Charles H. Baker interests; having proposed developments in Alabama estimated at 130,000 horsepower.

Commonwealth Power Company, together with the Grand Rapids-Muskegon Power Company (both under same interests), controlling 13 developed water powers in Michigan, with a total installation of 43,000 horsepower. A harmonious connection apparently exists with the Eastern Michigan Power Company, which controls all the power sites on the Au Sable River, Michigan.

United Missouri River Power Company, a holding company controlling at least three subsidiaries, which, with a closely related company, have five developed powers and one in construction, making a total of 57,500 horsepower.

Portland General Electric Company, with developments on the Clackamas and Willamette rivers amounting to 22,500 horsepower, near Portland, Oreg. A. C. Bedford, a director of the Standard Oil Company, is president, and F. D. Pratt, also of Standard Oil Company, is a director.

Pacific Gas and Electric Company. This is a very important holding company of the California Gas and Electric Corporation and the San Francisco Gas and Electric Company. These two latter companies in turn represent the consolidation or acquisition of the stock or property of over thirty power or power-distributing companies in California. They control 11 water-power developments, with a total installed plant of 118,000 horsepower.

Pacific Light and Power Company, with another company controlled by the same interests, known as the Huntington interests, represent eight developments in California, with a total of 30,000 horsepower. Henry E. Huntington is vice-president and Howard E. Huntington a director.

Edison Electric Company, with six developments in California and a total of 33,000 horsepower. This company is reported to have control of about 75 per cent of the available undeveloped water powers in southern California.

Hudson River Electric Power Company, a holding company for the Hudson River Water Power Company, Hudson River Power Transmission Company, Empire State Power Company, with developments at Spiers Falls and Mechanicsville on the upper Hudson, and Schoharie Creek near Amsterdam, N. Y., amounting to 45,000 horsepower installed, and sites owned in the Mohawk, Sacandaga, and upper Hudson valleys, amounting to 30,000 horsepower, or a total of 75,000 horsepower. C. Elmer Smith was director of the holding company to within a year.

Telluride Power Company, together with the Beaver River Power Company, controlled by the same interests, has 11 developments in Colorado, Utah, and Idaho, with a total present installation of 52,000 horsepower.

SUMMARY.

An estimate of the water power, developed and potential, now controlled by the General Electric interests, admitted or sufficiently proven, is about 252,000 horsepower; by the Westinghouse interests, similarly known, about 180,000 horsepower, and by other large power companies, 875,000 horsepower. This makes a total of 1,307,000 horsepower. Adding the horsepowers of the third class (*c*), those whose connection with these two great interests is at least probable, to wit, 520,000 horsepower, we have a small group of 13 selected companies or interests controlling a total of 1,879,000 horsepower developed and undeveloped.

Assuming that the water power at present in use by water-power plants in the United States is 5,356,000 horsepower, as estimated by the United States census and the Geological Survey from figures of installation, we see that approximately a quantity of horsepower equal to more than 35 per cent of that amount is now probably controlled by this small group of interests. Furthermore, this percentage by no means tells the whole truth. The foregoing powers naturally represent a large proportion of the best power sites. These sites are strategic points for large power and market control. Poorer sites will not geenerally be developed until these strategic sites are developed to their full capacity. And should these strategic sites be "coupled up" they become still more strategic. There are powerful economic reasons for such coupling. The great problem of water-power companies is not only that of the "uneven load," common to all power companies, but especially that of an uneven source of power, because of the fluctuating flow of the stream. A coupling up utilizes not only the different storages in the same drainage basin, but, of still greater import, the different drainage flows of different basins. Also, by coupling up, powers which have largely "day loads" can at night help out other powers which have largely "night loads," and vice versa. Coupling up is rapidly in progress in the United States. The Niagara Falls Power Company and the Canadian Niagara Power Company are coupled. The Southern Power Company, in North Carolina and South Carolina; the Commonwealth Power Company, in Michigan; the Pacific Gas and Electric Company, the Pacific Light and Power Company, and the Edison Electric Company, in California—each concern has its various developments coupled up into one unit.

The economic reasons urging water-power concentration are thus obvious. The facts set forth above show the very rapid and very recent concentration that has already occurred, practically all in the last five years. These economic reasons and business facts indicate clearly the further progress toward concentration that is likely to occur in the near future. It is obvious that the effect on the public of such present and future conditions is a matter for serious public consideration.

CONTROL OF CATCHMENT AREAS.

By Horatio N. Parker,

Water Resources Branch, United States Geological Survey.

Catchment areas, annual consumption, and total money investment of the water works of 42 cities which derive their water supplies from impounded surface waters and which have populations of over 30,000.

[a] Exclusive of a reservoir of 300,000,000 gallons capacity.

[b] Metropolitan Water Works.

[c] Exclusive of a storage reservoir in Acushnet, which has a catchment area of 5.25 square miles.

[d] An additional storage reservoir of 1,600,000,000 gallons capacity is under construction.

[e] On Croton, Bronx, and Byram rivers.

[f] On Croton River, including the new Croton reservoir to be finished in 1911, and on Bronx and Byram rivers.

[g] 1832 to 1898, inclusive.

[h] Exclusive of Hemlock Lake.

[i] Little River supply, now 40 per cent completed, is to replace present supply; will have a catchment area of 48 square miles and storage capacity of 2,600,000,000 gallons.

[j] Amount spent since the works were taken over by the city in February, 1902.

[k] Original, 4,017,500.

ORIGINAL FORESTS.

By R. S. Kellogg,
United States Forest Service.

The original forests of the United States exceeded in the quantity and variety of their timber the forests of any other region of similar size on the globe. Five great forest types were distinguished—the northern, southern, central, Rocky Mountain, and Pacific coast. Their boundaries are roughly sketched in the accompanying diagram.

The northern forests extended from Maine through New England, across New York and considerable of Pennsylvania, through the main portions of Michigan and Wisconsin to Minnesota, with an extension along the high Appalachian ridges as far southwestward as northeastern Alabama and northern Georgia. Roughly, it covered some 150,000,000 acres. In this forest the cone-bearing trees predominated. It was the home of the white pine. Associated with it were red pine, spruce, hemlock, cedar, balsam fir, the birches, black cherry, sugar maple, and several other hardwoods of minor importance. The total stand of timber of all kinds in the northern forest originally was not less than 1,000,000,000,000 board feet.

The northern extremity of the southern forest was in southern New Jersey, widening out southward and westward to cover much of Virginia, nearly all of North Carolina and South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, with a portion of eastern Texas and southern Arkansas, and a small extension into southern Missouri. This, too, was a coniferous forest. The yellow pines predominated heavily. Interspersed with the pines in localities suitable for their growth were cypress, oaks, gums, magnolia, yellow poplar, and a variety of other hardwoods. The total original area of this forest was perhaps 220,000,000 acres, and it contained at least 1,000,000,000,000 feet of merchantable timber.

In rough outline, the central forest stretched from the Atlantic coast to the prairies, with limitations on the other two sides by the northern and southern forests. There were no sharp demarcations between it and the other types, and it was extremely irregular in shape. It was the only forest region of the United States in which the hardwoods predominated, and they occurred in extreme abundance. Walnut, oak, elm, hickory, cottonwood, maple, basswood, chestnut, sycamore, red gum, ash, and many other trees here reached their maximum development. It can be conservatively estimated that the original area of the central hardwood forest was not less than 280,000,000 acres, and that the amount of merchantable timber standing upon it before clearing began was at least 1,400,000,000,000 board feet.

The Rocky Mountain forest, as its name indicates, was typical of the Rocky Mountain region from Idaho and Montana through Wyoming, Utah, and Colorado to Arizona and New Mexico. It was separated by the prairie and the plains region from the eastern forests and by desert areas from the Pacific forest. This forest grew chiefly on the higher plateaus and mountain slopes and was almost entirely coniferous. Western yellow pine occurred throughout, while lodgepole pine, larch, spruce, Douglas fir, giant arborvitæ, and other softwoods were abundant in many localities. The broken character of this forest makes the timber and area extremely difficult to estimate. It is probable, however, that the original extent was not less than 110,000,000 acres, and that it contained 400,000,000,000 board feet of merchantable saw timber.

The Pacific type of forest characterized California, Oregon, and Washington, reaching its maximum development along the Sierras and west of the Cascade Range. So far as saw timber was concerned it was almost exclusively a coniferous forest, and consisted chiefly of Douglas fir, western yellow pine, redwood, giant aborvitæ, sugar pine, and various other firs and spruces. The original area of this forest was at least 90,000,000 acres, and the amount of merchantable timber which it contained was not less than 1,400,000,000,000 board feet.

Without exaggeration, then, we may say that the original forests of the United States covered 850,000,000 acres and contained 4,800,000,000,000 board feet of merchantable saw timber according to present standards of utilization. In addition there were probably 150,000,000 acres of scrubby forest and brush land, chiefly in the West, which has been and still is a source of much post and fuel material.

FIG. 1.

STANDING TIMBER IN WOOD LOTS.

By **Wesley Bradfield.**
United States Forest Service.

The amount of woodland owned by farmers in the United States, together with the amount of stumpage which they control, bears a very important relation to the total amount of timberland and the total resources of the country. Although the estimates given in this report are subject to revision, they are as nearly correct as may be obtained at the present time.

It is estimated that the farmers own 38 per cent of the total area of forest land and 12.4 per cent of the total amount of merchantable timber. On the average, not more than 30 per cent of these resources reaches the general timber markets of the country; this amount affects only local sections, as the greater percentage of the timber cut from farmers' wood lots is consumed in the vicinity of cutting. This percentage is practically all that can be relied upon at the present time from this source of ownership to aid in meeting the general market demands. For, while a certain percentage of young timber is gradually reaching a merchantable size, the acreage in farmers' holdings is gradually decreasing, mainly through the clearing of woodland for agriculture, and the amount of timber available for the future is more rapidly decreasing, because the farmer's wood lot is by no means reserved entirely for the production of a future supply for the owner or for the local markets. A far more important place, however, is held by the wood lot in that it provides a great amount of timber of all sorts needed on the farm for rough building, general repairs, fences, and fuel. This timber is not always used to the best advantage, and it is very evident that if this source of supply were more carefully managed, the influence which the farmers' holdings have on the general market would be much greater than at the present time.

It is estimated that in the whole United States the farmers own over 204,000,000 acres of woodland, 46 per cent of which contains merchantable timber, 43 per cent cord-wood timber, and 11 per cent is in brush land. The estimated stand on these holdings is 311,000,000,000 feet of timber and 1,500,000,000 cords of wood.[a] Its distribution throughout the eastern and western halves of the United States is shown by the following table:

---

[a] In addition to approximately 1,000,000 cords of wood on the second type of woodland, there are also half a million cords of wood on the merchantable timbered area not included in the tabular estimates.

Percentage of total area of section owned by farmers.

	In the East.	In the West.
Per cent of total woodland	52	7
Per cent of total acreage	94	6
Per cent of wood-lot area containing merchantable timber	43	83
Per cent of wood-lot area containing cord wood	45	14
Per cent of wood-lot area in brush land	12	3
Per cent of stand of timber in wood lots	74	26
Per cent of cord wood in wood lots	99	1

This table shows that in the eastern half of the United States the percentage of the total amount of woodland owned by the farmers is about one-half of the total timber acreage in that section of the country. The relative importance of the farmers' holdings in the western half is very small, as they own only 7 per cent of the total timber acreage, and practically none of their timber has any effect on general market conditions. Provided that the quality of the timber remains the same, the money value of the farmers' wood-lot holdings represents even the smaller proportion in its relation to the total value of the timber stumpage, as these holdings are isolated and can be exploited only at a cost which is greater in proportion to the expense of marketing the timber held by all other sources.

The relation of the farmers' wood lot to the total forested area throughout the United States is given in more detail in the following groups of States:

In the New England States, together with New York and New Jersey, 47 per cent of the forested area is held by farmers. Of this amount 29 per cent is merchantable timber land, 54 per cent is cord-wood-timber land, and 17 per cent is brush land. The stumpage owned by farmers is approximately 15,798,000,000 feet and over 96,000,000 cords of wood. The general quality of the merchantable timber is of medium grade. The predominating species are the oaks and chestnut; spruce and white pine; maple, birch, and hickory. The cord-wood land in this and in all of the following sections represents a potential future timber production of very great importance, as the forests on this cord-wood land, so called, is rapidly growing into the merchantable timber class.

In the States of Delaware, Maryland, and Virginia, 81 per cent of the woodland is owned by farmers, of which 42 per cent contains merchantable timber, 50 per cent is cord-wood timber land, and 8 per cent is brush land. The stand of timber in these States is approximately 15,634,000,000 feet and 49,000,000 cords of wood. The quality of the merchantable timber is poor. The predominating species are the oaks, chestnut, maple, beech, hickory, and basswood, with scattered stands of loblolly pine, pitch pine, and scrub pine.

In the South Atlantic and Gulf States 50 per cent of the woodland is owned by farmers, of which 48 per cent contains merchantable timber, 40 per cent is cord-wood land, and 12 per cent brush land. The stand of timber in wood lots is approximately 110,426,000,000 feet and 332,000,000 cords of wood. The quality of the merchantable timber is good. The predominating species are longleaf, shortleaf, and loblolly pine, and cypress along the coastal plain; oaks, beech, maple, and other hard woods throughout the mountain section.

In the States of Pennsylvania, West Virginia, Kentucky, and Tennessee 62 per cent of the woodland is owned by farmers, of which 38 per cent contains merchantable timber, 50 per cent is cord-wood land, and 12 per cent is brush land. The stand of timber is approximately 33,332,000,000 feet and 111,000,000 cords of wood. The quality of the merchantable timber is poor. The predominating species are the black oaks, beech, maple, white oak, chestnut oak, chestnut, and hickory in the mountain regions, and black oak, beech, white oak, hickory, gums, and maple in the better agricultural regions.

In the Lake region the farmers own 40 per cent of the timber-land area, of which 40 per cent contains merchantable timber, 41 per cent is cord-wood land, and 19 per cent is brush land. The stand of merchantable timber is approximately 24,003,000,000 feet and 119,000,000 cords of wood. The quality of the merchantable timber is good. The predominating species are the oaks, elm, basswood, hickory, maple, beech, birch, white pine, Norway pine, and jack pine.

In Arkansas and Missouri 49 per cent of the timber-land area is owned by farmers; of this acreage 51 per cent contains merchantable timber, 43 per cent is cord-wood land, and 6 per cent is brush land. The stand of timber is approximately 20,748,000,000 feet and 70,000,000 cords of wood. The quality of merchantable timber is poor. The predominating species are black, post, pine, white, and chinquapin oaks, sycamore, gums, and elms.

In the prairie States, which contain only a small percentage of timber land in comparison with their total area, the farmers own 70 per cent of the woodland. Of this amount 37 per cent contains merchantable timber, 48 per cent is cord-wood land, and 15 per cent is brush land. The stand of timber is approximately 11,799,000,000 feet and 51,000,000 cords of wood. The quality of the merchantable timber is poor. The predominating species are the oaks, maple, elm, sycamore, cottonwood, and birch. All of the above States are included in the eastern half of the United States.

In the West the farmers own only 7 per cent of the total acreage of forest land, of which 83 per cent is merchantable timber land, 14 per cent cord-wood land, and 3 per cent brush land. The stand of timber on farmers' holdings is approximately 79,480,000,000 feet and 9,000,000 cords of wood. To show more definitely the relation between the farmers' holdings in the East and the West, the eastern half of the United States contains 94 per cent of the total acreage owned by farmers, 89 per cent of the wood-lot area which contains merchantable timber, 98 per cent of the wood-lot area containing cord wood only, 99 per cent of the brush-land area, 74 per cent of the total amount of stumpage owned by farmers, and 99 per cent of the total amount of cord wood on farmers' holdings.

Although the amount of standing timber in wood lots is comparatively small, it is very evident that the supply of timber which may be derived from farmers' wood lots can be greatly increased over the present percentage of merchantable timber which the farmers place on the market. Over one-fourth of the wood-lot area in the eastern half is in or adjacent to coal and gas regions, where the demand for firewood for local consumption is very small. For this reason it is estimated that over 50 per cent of the wood-lot area need not be depended upon to furnish the local supply of fuel. The demands of the farmer on the average wood lot for building material, fence posts, and other incidental timber uses on the farm are not very great in proportion to the total amount which the farmers' wood lots contain. At the present time a rather indiscriminate use is made of the timber in farmers' wood lots, and but little attention is paid to other than the immediate demand of the owner and to what material can be most easily secured to meet this demand. It is safe to say that, of the timber acreage alone, from 50 to 60 per cent could be safely counted upon to meet local demands other than those of the owners themselves.

The present rate of production of timber in farmers' wood lots does not exceed 30 cubic feet of wood per acre per year throughout the eastern half of the United States. In a great many sections the actual production of cubic feet per acre per year is exceedingly small, or perhaps nothing at all. This is because the wood lots in many cases contain a very high percentage of mature timber which has reached its maximum productive capacity, or because the farmers' wood lots are also used for pasturing and other purposes which greatly decrease the normal amount of annual production which would otherwise be obtained.

As a rule, farmers' wood lots may be said to occupy excellent sites for timber growing, as the character and fertility of the soil and the moisture which the soil contains are practically the same as that of the agricultural land on the remaining parts of the farms, and in many cases differ only from the remaining parts of the farms in being land which is too rough to cultivate. The unit of production on the wood lots in the eastern half of the United States should average from 60 to 70 cubic feet per acre per year. This would practically double the amount of timber which might be placed on the market over that which is now sold locally, while with greater care in the local use of the timber needed on the farm the amount of timber which might be placed on local markets would even be much greater.

Thus it will be seen that the relation which farmers' holdings bear to the total timber acreage in the country and the proportionate amount of timber with which they supply the local markets is very important, especially throughout the eastern half of the United States. Should their proportionate timber acreage slightly decrease every year, an increased production of over 100 per cent may be obtained on their future holdings. Wood-lot timber is cut more conservatively than the timber of other holdings in the East and may become a more important factor in the question of furnishing local timber supplies than it is at the present time. This demonstrates the very great need of more conservative and more intensive management of the timber land owned by the farmers in the United States.

This can only be brought about by the farmers themselves. They should be more thoroughly acquainted with the way in which to better care for and grow their timber supplies as well as the marketing of the timber which they now own.

Wood lots.

STAND OF TIMBER.

By **Herbert Knox Smith,**
Commissioner of Corporations.

The field work of the Bureau of Corporations on the quantity of standing timber covered those parts of Virginia, North Carolina, South Carolina, and Georgia, south and east of the mountains, and the timbered parts of the following States: Florida, Alabama, Mississippi, Louisiana, Texas, Arkansas, Missouri, Michigan, Wisconsin, Minnesota, Montana, Idaho, Washington, Oregon, and California.

The estimate of the total amount of privately owned merchantable standing timber on this entire area, obtained by the methods described below, on the basis of product of lumber under present conditions, is 1,570,000,000,000 board feet. The Forest Service has estimated the standing timber on the forest reserves at 390,000,000,000 board feet; that on the unappropriated public lands, national parks, and Indian reservations, 59,000,000,000 and that on the state lands, 35,000,000,000. These figures, together with that obtained by the Bureau of Corporations, give a total of about 2,050,000,000,000 board feet. No detailed investigation has been made for the privately owned timber outside the area covered by the Bureau of Corporations, but the Forest Service has made a tentative estimate of 450,000,000,000 feet for it, making the total standing timber in the United States about 2,500,000,000,000 board feet.

A systematic inquiry into the amount of standing timber in the United States might be made by either of two methods; first, to examine the entire timber area of the country and thus obtain the information first hand. This would require a very long time and great expenditure. Even if cost were disregarded it would be practically impossible to secure a sufficient number of experts to finish the task within a reasonable time.

The second method is that of bringing together the best information on the subject now in the records of timber owners or within the personal knowledge of men engaged in the industry. Nearly all owners of important tracts have fairly good knowledge of the quantity of their timber, and they, together with others engaged in the timber and lumber business, are acquainted with the other timber in their several localities. From such sources quite satisfactory estimates on the total timber in the entire county, or in certain parts of it, such as townships, or on the total timber exclusive of specified large holdings, can be obtained. Thus the facts regarding large holdings can be secured, and an estimate on all timber in the county outside such holdings separately reported can be had by interviewing the men best informed on the county as a whole or on subdivisions of it. A comprehensive plan by which all of this information is brought together and compared, and the most accurate data for the various localities tabulated gives the best information regarding the timber supply which can be obtained under present conditions at reasonable cost.

The general plan adopted by the Bureau of Corporations was to obtain first a report from each owner of 50,000,000 board feet or more. This report included, among other items, the acreage and an estimate of the amount of timber in as great detail as could be had, and, wherever obtainable, the exact location of the land. When this information had been obtained it was so arranged as to show for each county the names of owners, locations of lands, and estimates, and from this the work was carried forward by securing general estimates on the total of all other holdings in the county. The constant effort was to secure the information in as much detail as possible, so that each man's judgment could be taken on the area with which he was most familiar. Thus, wherever practicable, these general estimates were made for the timber in the county exclusive of the large holdings previously obtained, and were also taken for subdivisions of the county, such as survey townships or political subdivisions. In case it was not possible to secure an estimate on all small holdings in such detail, the estimate was obtained on the total timber in the county, but in no case did the estimate cover a larger area than a county, although some individuals furnished separate estimates for a number of counties. The judgment of as many well-informed men as could be found was obtained for each county. A final estimate for the county was then reached by a consideration of all the evidence.

The chief difficulty in arriving at the amount of timber owned by those having 50,000,000 board feet and over is that all estimates are largely a matter of judgment, and their accuracy depends on the care used and the skill of the man making the estimate. Good cruisers often differ very materially on the same tract. Again, nearly all estimates are too low because most obtainable estimates were made for the use of buyers whose first care was for a safe judgment on the value of the property. Such estimates run all the lower because in many instances the buyers have needed only rough and partial estimates to assure them that they were getting at least enough timber to make them safe at the price paid, with the probability that there was considerably more timber on the tract.

Another difficulty is due to changes in the standards of merchantable timber as the price of lumber advances. Vast quantities of timber now counted as merchantable would not have been so counted fifteen years ago, and in some parts of the country an estimate made in 1900 must be greatly increased to represent the timber which is now merchantable. With higher prices more logs are brought to the mill from the same tract, and the manufacturer of lumber will make more board feet out of the same log because he is able to sell some boards not previously marketable. Again, some species of timber formerly regarded as worthless are now valuable. Therefore, it has been necessary to bring estimates made a number of years ago up to date. The date of the estimate and the conditions surrounding it were always secured, and the owner was asked what increase, in his judgment, should be made for such correction.

In addition to the statements furnished by the owner, other men having knowledge of the land were interviewed, and in many instances valuable information was obtained from those not directly interested in the property.

The general estimates on all small holdings in a county or on the total timber in a county are subject to varying percentages of error because of the imperfect knowledge of the informants. And while it is believed that such estimates are oftener too small than too great, they are not always so, and, therefore, to some extent at least, the error in one county is offset by an opposite error in another county.

Estimates on standing timber are not usually meant to give the most probable approximation to the quantity of lumber which would be produced at the mill, but instead a conservative approximation to the scale of the logs if cut, on which there would be an overrun at the mill. This point has been studied on the basis of answers to specific questions and also of general interviews with the best informed men; and for the principal subdivisions of the timber area percentages have been determined by which the totals of the estimates have been increased to cover both the error in estimates, as such, and the overrun from good estimates to mill output. Consequently the final figures are the best judgment obtainable from the investigation on the amount of lumber which would be produced from the merchantable standing timber if sawed under the conditions now existing in the lumber industry. Without question, as the price of lumber advances, a very considerable addition will be made to the supply of timber through the lowering of the standards of merchantable timber and the better use of such logs as are now sawed, but there is now no basis upon which this additional amount can be approximated.

The field work was a long and difficult task, and the office work necessary to judge carefully all reports on the vast area covered to determine the most accurate figures in cases of conflicting statements, and finally to compile the records thus established, has been much greater than would be judged offhand. There is inevitable error in statistical data on standing timber, and the best that can be done is to gather the information in as much detail as possible and from as many people as have knowledge of definite areas, and through an impartial study of all this material to arrive at the best possible approximation to the truth. It is believed that the errors in the results of this investigation are not large enough to affect materially their value for the purposes which they serve.

STANDING TIMBER OWNED BY THE STATES.

By J. Girvin Peters,
United States Forest Service.

The information regarding the stand of timber owned by individual States was obtained from state foresters and other state officials, and in a few cases from Forest Service officials. In many States the knowledge of the amount of timber owned is extremely meager, and the information furnished by a large majority was simply an estimate.

The total estimated amount of standing timber owned by the different States is 35,474,050,000 board feet, and the total area of State land forested is 9,460,622 acres.

The largest amount of timber owned by any State is that reported for New York, which is 8,600,000,000 board feet. Of the total amount reported by all the States, less than 10 per cent is hardwood. The bulk of the timber owned by the States located in the northern forest is spruce, white and Norway pine, hemlock, and cedar; in the southern forest, yellow pine; in the Rocky Mountain forest, western yellow pine, and in the Pacific coast forest, Douglas fir and redwood. The quality of the bulk of this timber is good, but not the best.

The following table shows the estimated amount of timber and forest land owned by the different States and Territories:

Estimated amount of standing timber and area of forest land owned by the different States and Territories.

State or Territory.	Amount.	Area forested.
	M feet B. M.	*Acres.*
Arizona	735,000	200,000
Arkansas	50,000	25,400
California	5,400,000	915,700
Colorado	680,000	572,800
Florida	625,000	250,000
Idaho	3,800,000	144,200
Maryland	250	1,957
Massachusetts	2,400	12,000
Michigan	480,000	120,000
Minnesota	2,519,900	2,695,187
Mississippi	170,000	180,800
Montana	1,158,900	1,000,000
Nevada	4,000	4,000
New Jersey	4,600	9,900
New Mexico	620,000	277,800

South Dakota	125,000	59,400
Washington	5,000,000	500,000
Wyoming	260,000	250,000
Total	35,474,050	9,460,622

STANDING TIMBER IN POSSESSION OF THE FEDERAL GOVERNMENT.

By G. M. Homans,
United States Forest Service.

The estimated amount of merchantable timber in the possession of the Federal Government, exclusive of Alaska, in its National Forests, Indian reservations, national parks, military reservations, and on unreserved public lands, is nearly 449,000,000,000 feet, b. m., and an unestimated amount of cord-wood, poles, posts, and mining timbers. Of this amount, over 86.7 per cent is within the national forests, 7.6 per cent within the Indian reservations, and over 3 per cent on the unreserved public lands. This material resource has an average value of $2.50 per thousand feet and represents a capital of $1,122,150,000.

The actual forested area now containing merchantable saw timber is approximately 92,629,500 acres, of which 81 per cent is national forests, 11 per cent Indian reservations, and 5 per cent unreserved public lands (Table 2).

In the Pacific coast region the stand per acre is much the heaviest and decidedly more variable. On the west slope of the Cascade Range selected acres of Douglas fir will often exceed 100,000 feet b. m., while on the east slope, in the yellow pine country, areas not exceeding 4,000 feet b. m. are very common. The average stand per acre is more uniform in the Rocky Mountain and eastern region since the forested area is comprised largely of pure stands and of species more uniform in volume.

The principal merchantable species in the Pacific coast region are, in the order of their predominance, Douglas fir, western yellow pine, white fir, hemlock, sugar pine, tamarack, redwood, and lodgepole pine. In the Rocky Mountain region the species having the greater commercial value are, in the order of their occurrence, lodgepole pine, yellow pine, Engelmann spruce, white fir, Douglas fir, western white pine, and cedar. The remaining merchantable area, with the exception of Arkansas and Minnesota, lies east of the Mississippi River, and the stand is composed chiefly of white pine, long-leaf and short-leaf pine, white oak, red oak, chestnut, basswood, birch, white ash, cypress, and other mixed hardwoods.

Although it is impossible to state accurately the amount of the more important species, yet it is estimated that the stand is composed of 30 per cent western yellow pine, 20 per cent Douglas fir, 10 per cent lodgepole pine, 7 per cent white fir, 5 per cent Engelmann spruce, 5 per cent western hemlock, 5 per cent cedar, 3 per cent tamarack, 3 per cent sugar pine, and 12 per cent of other species. Since the mixed hardwoods form such a small part of the total stand, they have been included in the percentages for other species.

FIG. 2.

Generally speaking, the quality of the timber in the possession of the Federal Government compares unfavorably with that in the possession of large companies and corporations. This is easily accounted for, since a large part of the unappropriated area lies at high altitudes, which are unsuited for the best growth and development of the several species.

The national forests comprise a merchantable timber area of 75,030,000 acres and support a stand of approximately 390,000,000,000 feet b. m.

The Indian reservations comprise a merchantable timbered area of 10,541,900 acres and contain approximately 34,000,000,000 feet b. m. On the whole, the timber on Indian reservations consists chiefly of yellow pine, piñon, and juniper, and is of better quality than that in the national forests, since these reservations have been created at the lower elevations and have included land better adapted for the most favorable growth.

The merchantable area of national parks is estimated to be 2,540,000 acres and contains 10,717,000,000 feet b. m. and 343,500,000 cords of wood suitable only for fuel. The kind and quality of the timber is similar to that in national forests, since they have been created in similar regions and in large part include areas at and above timber line.

Military reservations, in so far as they contain natural timber resources, are of practically no importance, since they have a merchantable area of but a little over 69,000 acres, supporting but 198,595,000 feet b. m. and 3,900,000 cords of wood suitable chiefly for fuel. The stand is composed chiefly of longleaf and shortleaf pine, Douglas fir, white fir, and mixed hard-woods. On the whole, the several species contain but little lumber of the high grades, which renders them useless for other than fuel and rough construction material.

There are approximately 4,450,000 acres of unreserved public timber land which supports approximately 14,000,000,000 feet b. m. and an unestimated amount of cordwood. This figure seems somewhat startling when one realizes that unappropriated timber land is not only subject to entry but is very much sought after on account of the diminishing supply and a corresponding increase in stumpage prices, yet it must be understood that the areas supporting this timber are in many instances so surrounded by patented land that a claim would be practically worthless for lumbering purposes, while in other cases the tracts are either too inaccessible or are of insufficient size to attract the average claimant. Since these timbered areas have thus far been rejected by claimants it follows naturally enough that this is practically the cull of the Government's national timber resources. The stand is open, scattered, and scrubby for the most part, and consists chiefly of the poorer quality of Douglas fir, hemlock, white fir, juniper, piñon, cedar, and lodgepole pine.

FOREST PRODUCTS.

By R. S. Kellogg.
United States Forest Service.

The annual value of the forest products of the United States at the present time is approximately $1,280,000,000. The principal items are shown below; the value in every case is stated in round numbers and is estimated at the point of production. Except where otherwise specified, all statistics given in this paper are based upon data collected by the Bureau of the Census and the Forest Service.

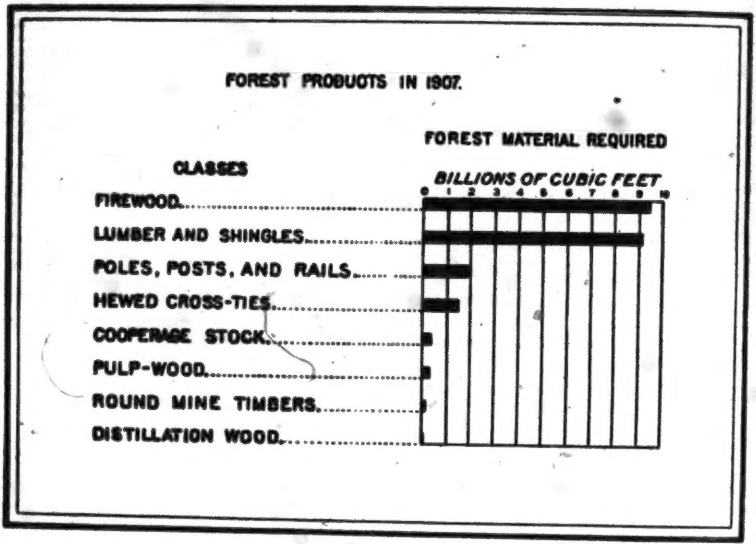

FIG. 1.

Product.	Value.	Product.	Value.
Lumber, shingles, and lath	$750,000,000	Pulp wood	$20,000,000
Firewood	250,000,000	Tanbark and extracts	15,000,000
Poles, posts, and rails	100,000,000	Round mine timbers	10,000,000
Hewed cross-ties	60,000,000	Miscellaneous	10,000,000
Cooperage stock	35,000,000		
Naval stores	30,000,000	Total	1,280,000,000

Nearly three-fifths of the total value of our forest products are made up of lumber, shingles, and lath, and a little less than one-fifth of firewood. No other group of products contributes as much as 10 per cent of the total.

The quantity of forest material required for these products under present conditions of logging and manufacturing is shown graphically in figure 1. The total exceeds 23,000,000,000 cubic feet. Of this, firewood takes about two-fifths, lumber and shingles slightly less, posts, poles, and rails about one-twelfth, and hewed cross-ties about one-sixteenth; relatively small quantities compared with the total cut of forest material required for other products.

LUMBER.

The cut of lumber, by kinds, in 1907, is shown graphically in figure 2, the total being 40,256,000,000 board feet. Yellow pine was in the lead, with 32.8 per cent of the total; Douglas fir ranked second, with 11.8 per cent; white pine third, with 10.4 per cent; oak, fourth, with 9.2 per cent; and hemlock fifth, with 8.4 per cent. Spruce and western pine furnished 4.3 and 3.8 per cent, respectively. These seven woods are the only ones from which over a billion feet of lumber are annually produced, and, taken together, they furnish more than four-fifths of our annual lumber supply.

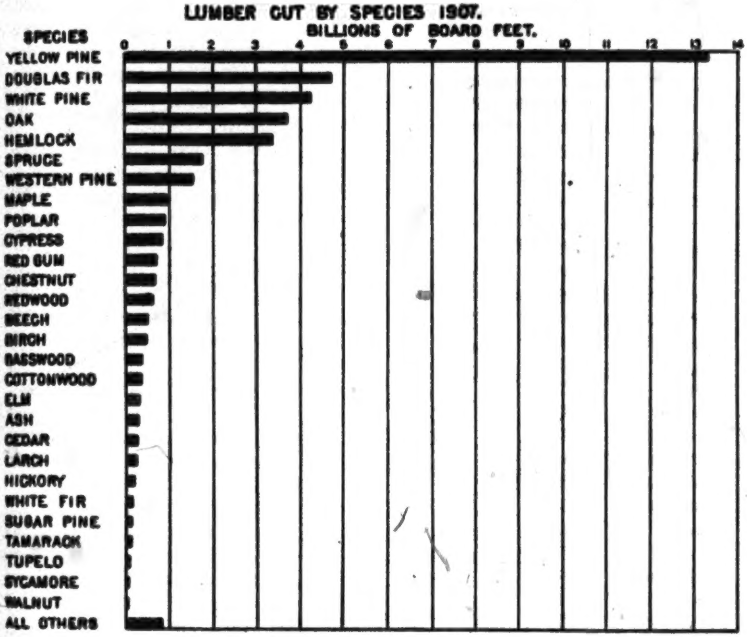

FIG. 2.

The softwoods as a group supplied 77 per cent of the lumber cut in 1907, and the hardwoods 23 per cent. The softwood cut, therefore was nearly three and one-half times as great as the hardwood cut. Though there was an increase of over 14 per cent in the total lumber production from 1900 to 1907, this was due chiefly to very heavy increases in the leading soft woods, particularly yellow pine and Douglas fir. At the former date the hardwoods supplied nearly 25 per cent of the total. During the seven years the output of yellow pine increased 36.8 per cent, that of western pine 61.7 per cent, that of cypress 52.8 per cent, that of redwood 58 per cent, and that of Douglas fir 173.4 per cent. These far more than counterbalanced the decrease of 45.8 per cent in white pine. On the other hand, the cut of the two leading hardwoods, oak and yellow poplar, decreased 16.2 per cent and 22.6 per cent, respectively, during this period. Remarkable increases took place in the output of some of the minor hardwoods, the gain in maple, for instance, being 48.4 per cent, in red gum 141.5 per cent, and in chestnut 215.5 per cent.

The lumber cut by States in 1907 is shown in figure 3. Washington, which ranked first, supplied 9.4 per cent of the total; Louisiana came second, with 7.4 per cent; Texas third, with 5.5 per cent; Mississippi fourth, with 5.2 per cent; and Wisconsin fifth, with 5 per cent. These five States are the only ones which cut two billion or more feet of lumber each in 1907, and taken together they furnished nearly one-third of the total production.

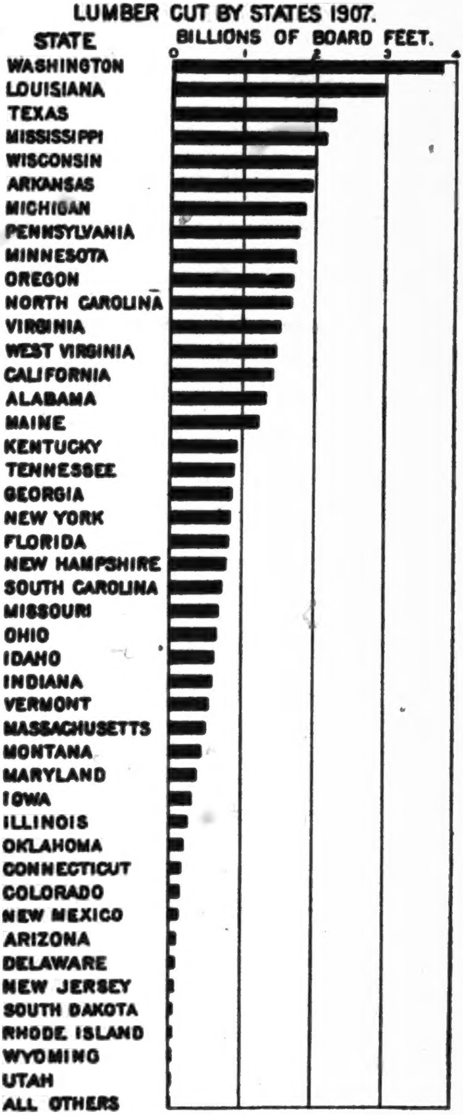

Fig. 3.

The relative production of lumber in ten States in 1880 and 1907 is shown in figure 4. In 1880 these States furnished 53.8 per cent of the total cut, and in 1907, 52.4 per cent, practically equal proportions, but the changes which have occurred in the output of individual States are most striking. Michigan, for example, furnished 23 per cent of the total in 1880, and but 4.5 per cent in 1907; Louisiana supplied but 0.7 per cent of the total in 1880, and 7.4 per cent in 1907; Washington cut but 0.9 per cent of the total in 1880, and 9.4 per cent in 1907. This diagram shows in vivid fashion the manner in which, with the cutting out of the virgin timber in the North and East, we have turned to the forests of the South and West for our lumber.

Figure 5 shows graphically the lumber production of the United States at census dates, from 1850 to 1907. The cut in 1907 was eight times that in 1850, and three times that in 1870. Notwithstanding the introduction of substitutes for lumber, our use of it has steadily increased up to the present time, the per capita consumption in 1850 being but 215 board feet, while in 1907 it was 470 board feet.

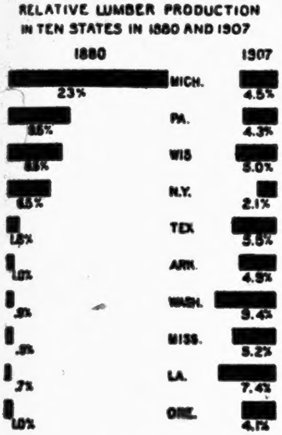

FIG. 4.

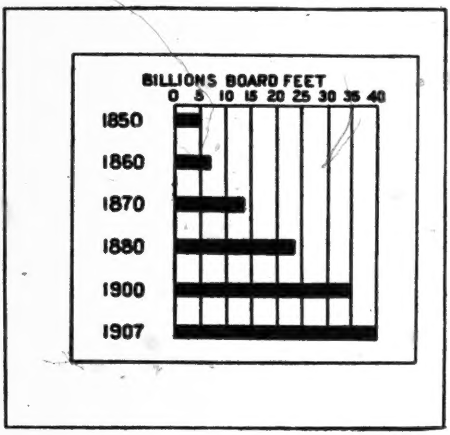

FIG. 5.

SHINGLES.

Many woods are used to some extent for shingles, but the market is dominated by cedar shingles, of which there are two kinds, the white cedar, or arbor-vitæ of the northeastern and Lake States, and the so-called "red cedar," or giant arbor-vitæ of the Pacific coast. Of the total production of 11,824,475,000 shingles in 1907, the western cedar supplied over three-fifths and the eastern cedar about one-tenth. Ten per cent of the shingles manufactured that year were of cypress, and 7 per cent and 5 per cent, respectively, of redwood and yellow pine. Much more cedar is used for shingles than for other purposes, while with other woods shingles are frequently a by-product of lumber manufacturing.

LATH.

Lath are usually a by-product of lumber manufacturing, and so do not of themselves constitute an additional drain upon the forests. While some lath are made from nearly every wood that is cut into lumber, the bulk of the 3,663,000,000 lath manufactured in 1907 was of white pine, yellow pine, hemlock, Douglas fir, spruce, and cypress.

FIREWOOD.

It is estimated that approximately 100,000,000 cords of wood, exclusive of mill waste, are used annually for fuel in the United States. The bulk of this is, of course, used for domestic purposes upon farms in the regions where wood is relatively cheap and abundant and coal difficult to obtain or high in price. A great deal of wood is used for fuel everywhere except on the Great Plains, where the almost utter absence of timber makes its use impossible. Much of it is cut from farmers' wood lots, and much of it is timber which has little value for other purposes. On the other hand, it is not uncommon to find good hard-wood timber which could be used for lumber or otherwise cut into firewood.

POLES, POSTS, AND RAILS.

Some 3,500,000 round poles, exceeding 20 feet in length, are used annually by telegraph, telephone, and other electric companies. Over three-fifths of these poles are of cedar and more than one-fourth of them of chestnut. Relatively small amounts of pine, cypress, and redwood poles are also used.

Probably 1,000,000,000 fence posts and rails are used annually upon the farms and ranches in the United States. While the cedar posts of the Lake States are shipped long distances, most of the posts and practically all of the fence rails are cut in the locality where they are used. Consequently, the timber of which they consist varies greatly, the effort always being, of course, to cut the kind that is the most durable. Wherever it grows, chestnut is a favorite wood for both posts and rails. Many posts are made from young, round timber. Rails are generally made from straight timber, of larger size, which splits well, and many posts are also split.

HEWED CROSS-TIES.

The steam and electric railway companies of the United States purchased more than 153,0[illegible],000 cross-ties in 1907, over three-fourths of which were hewed. Since sawed cross-ties are classed as lumber, they are not discussed here. The oaks, and chiefly the white oaks, supply over 45 per cent of the hewed ties, and the cutting of hewed ties from young oak trees is, with the exception of lumber, the most serious drain upon our oak forests. Over 22 per cent of the hewed cross-ties were supplied by the southern pines, about 7 per cent by cedar, and about 5 per cent by chestnut. Spruce, tamarack, western hemlock, and redwood are used in lesser quantity for hewed ties.

PULP WOOD.

Over 3,000,000 cords of domestic pulp wood were used in 1907, and in addition some 925,000 cords were imported from Canada. Of the domestic pulp wood, nearly three-fifths were spruce and almost one-fifth hemlock. The bulk of the remainder was poplar, with small quantities of several other woods. Nearly as much spruce is used for pulp as for lumber.

COOPERAGE STOCK.

Cooperage stock is of two distinct classes, tight and slack. While the production of the former is much less in quantity, it requires much higher grade timber. In 1907 there were manufactured 385,232,000 tight staves and 27,692,994 sets of tight heading. The slack cooperage output amounted to 1,175,977,000 staves, 106,074,000 sets of heading, and 490,570,000 hoops. Probably 90 per cent of the tight cooperage stock required the best quality of white oak for its production. A large number of woods are used for slack staves and heading, the most important being red gum, pine, elm, beech, and maple. Because of its strength and toughness, little but elm is used for hoops. Probably as much elm is used for staves and hoops as for lumber.

TANBARK AND EXTRACTS.

The tanneries of the United States used nearly 1,200,000 cords of hemlock and oak bark and more than 400,000 barrels of tanning extracts made from domestic bark and wood in 1907. Two-thirds of the bark was hemlock, and the balance oak. Two-thirds of the extract was made from chestnut wood, and most of the remainder from hemlock and oak bark. Nearly 130,000 cords of hemlock and oak bark were used in making extract.

In the earlier days of the tanning industry a great deal of hemlock was cut solely for its bark and the wood was left to rot in the woods. This was also true to a lesser extent of oak. These practices are not general at the present time, however. The manufacture of tanning extract from chestnut wood has increased rapidly within recent years, and at least 250,000 cords of wood were used for this purpose in 1907. There have also been marked increases in the importation of tanning materials, the most striking being that of the wood and extract of quebracho, a South American tree. Over 290,000 barrels of quebracho extract were used by the tanneries of the United States in 1907.

ROUND MINE TIMBERS.

Data gathered by the Forest Service and the Geological Survey in 1905, upon the use of timber in mines, show that the annual consumption of round mine timbers exceeds 165,000,000 cubic feet, and that hard woods consitute more than half the total. Like the making of hewed cross-ties, the cutting of round mine timbers takes large quantities of young timber, and in many localities constitutes a serious drain upon the forests.

NAVAL STORES.

In 1908 there were produced 36,000,000 gallons of turpentine and 4,000,000 barrels of rosin, of which Georgia and Florida supplied two-thirds. About one-half of the product is exported.

While the production of naval stores does not necessarily destroy the forests, the methods so far used in the majority of the turpentining operations, coupled with subsequent fires and windstorms, have resulted in the destruction of not less than 20 per cent of the forests worked.

MISCELLANEOUS PRODUCTS.

There are included under this heading such forest products as maple sugar and sirup, timber which is exported in the log, and wood used for distillation, whose total annual value is easily $10,000,000. More than 1,280,000 cords of wood were used for distillation in 1907. With the exception of about 60,000 cords of pine, this wood consisted of hard woods, chiefly birch, beech, and maple. No detailed information is available upon either the kind or quantity of logs exported, though the reports of the Bureau of Statistics show their value to be more than $3,000,000. Probably more walnut is exported in the log than any other timber which is sent out in this form.

RATE OF FOREST GROWTH.

By E. A. ZIEGLER,
United States Forest Service.

PRESENT TIMBER PRODUCTION.

The very existence of a problem of forest conservation is dependent upon the question of timber production. If production falls below consumption at present or threatens to in the future, the problem is very real. If the production exceeds consumption there is obviously no problem of conservation to solve. What data we have, therefore, on tree growth and wood production deserve careful study.

An idea of our present timber production requires, in the absence of records, information (1) on the rate of growth in diameter and height of the individual species composing our forests; (2) on the production per acre when a normal number of trees is present (i. e., when the land is fully stocked), and (3) on the condition for growth of the present forest. This (3) requires the classification of forest lands roughly into (*a*) nonproducing forest land which includes that covered with mature forests, as well as that not producing through lack of trees, and (*b*) the producing forest land with its present stocking, whether cut over, culled over, or burned. Applying the average growth per fully stocked area to the area of producing forest and multiplying by the average per cent of stocking would give the total growth. It is very difficult to secure definite data showing the average restocking of second-growth forests of the country, however, and on this point it may be necessary to accept expert judgment supported by studies of specific areas.

THE RATE OF GROWTH OF INDIVIDUAL SPECIES.

Studies on the rate of growth of different species giving the diameter and height at different ages have been made and are here summarized. These studies were largely made on trees cut in virgin forests, where their development under the shade of a preceding generation of trees may have been slower than if they had been given the better light conditions of a clearing or heavy culling. To what degree the changed condition of light, soil, etc., following lumbering affects subsequent growth is not definitely known,[a] though the diameter growth of individual trees is frequently increased, but often a poorer quality of material is produced. This is caused to some extent by too few trees per acre, which reduces the acre yield in the face of faster diameter growth in the individuals.

---

[a] The increased growth due to removing mature trees in a spruce forest in New York was found to be about 13 per cent for the first five years after lumbering.—"The Adirondack Spruce," page 45, Pinchot.

The growth given is of course an average. White pine on lower slopes in New York is said to have an average diameter of 10.6 inches in fifty years. The largest number will be from 9 to 12 inches in diameter, though a few may be 15 inches or even more, and many trees will fall much below that figure.

The summaries are grouped in the form of regional tables:

Table 1, showing diameter and height growth in northern forests.

Table 2, showing diameter and height growth in central hard-wood forests.

Table 3, showing diameter and height growth in southern forests.

Table 4, showing diameter and height growth in Rocky Mountain forests.

Table 5, showing diameter and height growth in Pacific coast forests.

Both the common and botanical names are given, as well as the locality and so-called forest type where the measurements were made. The diameter and height at different ages follow.

Different studies made on the same species show varying rates of growth, so to avoid the bulky mass of detail a selection was made of the more representative data and the rest added in an appendix. When only one study was made, and the growth hardly seems representative of the species, note is made of it.

A study of the tables will reveal large differences in rate of growth in diameter and height between different species, but a full comparison should include the number of trees per acre also. That is, the production per acre must be the final index in determining desirable species, rather than rapidity of diameter or height growth which may be offset to some extent by the stand per acre.

TABLE 1.—*Approximate average rate of growth for northern forests.*

[a] These species were undoubtedly suppressed for some years.

NOTE.—The diameter given is 4.5 feet from the ground.

NORTHERN FORESTS.

This region embraces New England, New York, and the lake States of Michigan, Wisconsin, and Minnesota, and part of the Appalachian highlands extending farther south. It is marked by the presence of the white pine as the principal species. Red spruce in the east, red pine in the west, and hemlock through a large part of the region are important conifers, with arborvitæ, tamarack, and jack pine of less importance. Birches, beech, elm, aspen, basswood, and maples are rather important hard woods.

In growth, white pine leads except for jack pine and aspen in the first thirty years. Red pine in Wisconsin and Minnesota seems to exceed it in that part of the range with an excellent growth. Since jack pine is a small tree when mature its growth falls off rapidly before reaching even tie size. Spruce is rather slow growing, but arborvitæ, tamarack, hemlock, and balsam fir are still slower. Aspen and basswood grow rapidly, as does paper birch under favorable conditions. Beech, sugar maple, and yellow birch are rather slow growing. The figures for beech, hemlock, and sugar maple seem to show a suppression during early life, and further studies under different conditions may show a more rapid growth, though at best they grow slowly.

CENTRAL HARD-WOOD FORESTS.

The central hard-wood forests are found mainly on the west and east slopes of the Alleghany Mountain plateau. They have been largely removed from Illinois and Indiana, so Tennessee and Kentucky show their best development at present. Yellow poplar is the most rapid-growing species and furnishes a good example of growth, as it varies under different conditions of virgin forest and second growth, the latter under very favorable conditions. Chestnut is a very rapid grower and has next place. Since valuable for posts, poles, and ties in small sizes, it holds forth great promise to the wood producer. Red oak, black oak, and white oak follow in the order named when grown from sprouts. Hickory approaches white oak in growth.

Farm timber plantations in Illinois show an excellent growth for silver maple for fuel, catalpa and European larch for posts and poles, and black walnut, under an eighty to one hundred year rotation, for timber.

TABLE 2.—*Approximate average rate of growth for central hardwood forests.*

		Virginia	Second growth in open—Quality I—seedling.	9.7	64	15.2	83								

[a] These species were grown in plantations on farm land, and have a correspondingly faster growth than the other forest-grown species. (See For. Ser. Cir. 81.)

NOTE.—The diameter given is 4.5 feet from the ground.

SOUTHERN FORESTS.

Southern forests include mainly the southern pine belt and the hard woods found along the rivers and coast, where cypress adds another important conifer.

The three principal southern pines, longleaf, shortleaf, and loblolly, make up the bulk of the southern forests and should play an important part in the future timber production of the country. Loblolly grows very rapidly and will produce a good crop of ties in forty years. Longleaf and shortleaf are both much slower growers, though longleaf gives excellent reproduction where fires do not run. Shortleaf occasionally exceeds longleaf in growth. The restocking of the cut-over pine forests is especially deficient on account of fire. Cypress makes a rather slow growth at first, but increases it to a considerable age, so that for a long period rotation it exceeds many other species. The natural reproduction is almost entirely wanting, however.

Eastern red cedar in locations between the pine and southern Appalachian hard-wood belts shows a fair growth and promises well for management.

The bottom-land hard woods contain several species of almost phenomenal growth. Cottonwood here shows a greater growth than any other native American species, producing timber of saw size at thirty to forty years of age. Red gum and white and green ash also do remarkably well on the lowlands.

TABLE 3.—*Approximate average rate of growth for southern forests.*

NOTE.—The diameter given is 4.5 feet from the ground.

ROCKY MOUNTAIN FORESTS.

The Rocky Mountain forests are entirely coniferous when the important species are considered.

Western yellow pine is the predominating species, and, excepting possibly Douglas fir, is the most rapid-growing species.

Lodgepole pine grows rather slowly, though it reproduces with a dense stand.

Engelmann spruce shows very slow growth in the study in Colorado.

No growth data have been collected on western larch, white fir, or silver pine—other important trees of the region.

The central fact in tree growth in this section is its slowness, which contrasts sharply with the rate of growth on the Pacific coast.

TABLE 4.—*Approximate average rate of growth for Rocky Mountain forests.*

NOTE.—The diameter given is 4.5 feet from the ground.

PACIFIC COAST FORESTS.

The important species are here again all conifers, though with a growth greatly exceeding that of the Rocky Mountains. The Douglas fir produces an excellent growth and holds much promise for the future. Redwood in California equals or exceeds the fir in growth, with an added advantage of reproducing from stump sprouts. Western yellow pine ranks third in growth among the important species, though it is finally overtaken by sugar pine. Western hemlock holds fifth place.

No study of growth has been made on western red cedar or the less important spruce, firs, etc., except on the white fir in Siskiyou County in northern California, which reveals a rather slow growth in this locality. Western yellow pine and Douglas fir furnish a comparison between the Rocky Mountain and coast regions.

Eucalyptus globulus, or blue gum, introduced into southern California from Australia, grows at the rate of almost an inch in diameter and 5 feet or more in height per year from the seed, and sprouts exceed even this phenomenal growth. As a wood producer in favorable localities free from frost it has no equal.

TABLE 5.—*Approximate average rate of growth for Pacific coast forests.*

[a] The diameter given is 4.5 feet from the ground, except for Douglas fir, which is for a stump height a little higher than 4.5 feet.

[b] An exotic introduced from Australia and widely planted for wind-break and fuel purposes in southern California.

From the preceding growth summary and the tables of the appendix the following table has been derived, estimating the time required to produce different wood crops. The periods of time are again averages often derived from growth in virgin forests and may be lowered slightly under the best second-growth conditions.

The average diameter at which timber may be best utilized for posts is assumed to be 6 inches, which means a range possibly of from 4 to 8 inches. Among the species commonly used in the East, chestnut (twenty years) is very rapid growing, but is equaled by catalpa in the Middle West farm plantations. White oak (thirty-five years) and eastern red cedar (thirty-five years) have a fair rate of growth. Northern white cedar, or arborvitæ (eighty years), grows exceedingly slowly. When the use of preservatives becomes more common, such species as red and black oaks (twenty-five years), loblolly, jack, red and white pines (twenty to thirty-two years), and yellow poplar (twenty years) may be used to good advantage, since they have rapid growth.

In the West data for cedar are wanting. Redwood (twenty years), however, will be a good producer. Assuming preservative treatment, yellow pine and Douglas fir (twenty-five years) promise well toward the coast, as does lodgepole pine (forty years) in the Rockies, for which the large number of trees per acre offset somewhat its slower growth.

Redwood [b]	do	20	25	35	50	70

[a] Species growing under favorable conditions when measured.

[b] Species tolerant of shade which should show better results in second growth.

For handle and vehicle wood (6 to 10 inch trees) white and green ash in the southern valleys and bottoms promises well (thirty years). Hickory requires sixty-five years, though it may be used in smaller sizes at an earlier age. Hard or sugar maple in second growth should be ready earlier than the ninety years indicated by virgin forests. White oak from sprouts will reach 8 inches in about forty-five years.

For pulp wood (6 to 10 inch trees) red spruce will require about eighty-five years. Hemlock and balsam fir are still slower growing. Cottonwood in southern bottoms seems worth serious consideration as a future source of supply by planting, since studies thus far made show it will produce 6 to 10 inch pulp wood in fifteen years in those localities. Aspen in the North in forty years is a better grower than spruce, unless the fewer trees per acre will offset the better growth. Yellow poplar in the South (Virginia) in second growth often produces wood of pulp-wood size in twenty-five years, yielding in that period 23 to 35 cords per acre if the trees are closely spaced. If methods of utilizing the pines for pulp are improved, loblolly pine (twenty-five years) and jack and scrub pines (forty years) might receive some attention.

Chestnut extract wood may be produced in twenty-five years. Paper-birch spool wood in fifty years, for 6 to 10 inch wood.

For mine props red oak requires thirty years, black oak thirty-five years, and white oak forty-five years; red pine forty years, loblolly pine twenty-five years; western yellow pine in the Rocky Mountains fifty years; Douglas fir and western yellow pine on the west coast thirty-five years. For other species see Table 6.

Railroad ties of white cedar (arbor vitæ) require as much as one hundred and fifty years to produce them in the cedar swamps of the North. Tamarack requires a similar period. Eastern hemlock is also very slow growing in virgin forests, requiring one hundred and thirty years. Beech does a little better, with one hundred years. These species may be bettered somewhat in second growth, but can not approach chestnut, which in forty years will produce good ties; red oak in forty-five years; white oak will require eighty years, though in favorable localities from sprouts possibly a little less time will be required. Mixed oaks in sixty years will produce from 100 to 200 ties per acre. Red and white pine do very well in a fifty-five-year period, but loblolly pine will reach tie size in forty years and produce 160 to 400 ties per acre, according to the number of trees present at this time. Longleaf pine will require seventy-five years to produce a crop of ties; cypress sixty-five years. Red gum, if treated and properly handled, will make a good tie, and will produce a crop in thirty to thirty-five years in southern lowlands, where it is native.

Rocky Mountain species grow slowly, with little chance of tie production in less than an average of seventy-five years, except in very favorable localities. On the Pacific coast Douglas fir and western yellow pine will produce ties in forty-five years in favorable locations, and redwood sprouts in even less time.

For poles and piles chestnut leads in the East. Loblolly pine does excellently and red pine fairly in Minnesota. On the Pacific coast Douglas fir, western yellow pine, and redwood produce good-sized poles in fifty to fifty-five years. Judging from its growth in plantations in Illinois, European larch should produce poles in a short period. Eucalyptus globulus (blue gum) in southern California will produce material of this size in fifteen years and in even less time from sprouts in the best situations.

For saw timber an average diameter (always at 4.5 feet from the ground) of 18 inches is taken, and would mean a range of from 10 to 24 inches and a sprinkling of even larger trees. This is, of course, a smaller tree than the average of many species now cut. The future timber crops will, however, be largely composed of smaller trees, since it will not pay to wait for the large dimensions. Among the species producing timber of this average size in ninety years or less might be named white pine (ninety), chestnut (eighty-five), ash (eighty-five), cottonwood (thirty), cypress (ninety), red gum (fifty-five), loblolly pine (seventy), Douglas fir (seventy-five), western yellow pine (eighty), and redwood (seventy). Yellow poplar, red oak, sugar pine, and red pine will also, under good conditions, fall under this mark. The other species studied are slower growing.

ACRE YIELDS.

The production of a number of species in fully stocked (dense) natural second-growth stands may be seen from the following tables. Since the average second-growth forest of the country is clearly not as dense as it should be, and these figures show actual production only on occasional areas, the average production will fall far below these figures. The tables show rather the possibilities under forest management. Quality II locations are selected as representing an average rather than Quality I. To reduce the cubic-foot yield to cords, divide by 90, and to reduce to board feet, Scribner rule, multiply by 3 (for 10-inch trees) or 4 (for 16-inch trees). The actual saw cut should exceed this in straight sound trees.

TABLE 7.—*White pine*[a]*—Quality II—Southern New Hampshire.*

Age.	Trees per acre.	Mean diameter.	Mean height.	Acre yield.	
	Number.	*Inches.*	*Feet.*	*Cubic feet.*	*Board feet.*
40 years	870	6.8	52	5,800	....
50 years	510	9.0	66	7,300	20,000
60 years	380	10.7	76	8,500	25,000
70 years	310	11.9	84	9,150	30,000
80 years	260	12.9	89	10,300	35,000
90 years	220	14.5	93	11,000	41,000

[a] Data collected by L. Margolin.

White pine is seen to be one of the best timber-producing species in the forest, keeping up a high rate of increase to a considerable age. The larger number of trees per acre enable it to produce as well or better than the faster-growing loblolly pine, yellow poplar, and chestnut of the East.

TABLE 8.—*Loblolly pine in eastern Texas.*

Age.	Trees per acre.	Mean diameter.	Mean height.	Acre yield.	
	Number.	*Inches.*	*Feet.*	*Cubic feet.*	*Board feet.*[a]
20 years	405	6.1	45	2,600	6,500
30 years	185	9.5	65	3,200	7,450
40 years	150	12.4	85	3,700	9,300

[a] Herring rule.

This yield of second-growth loblolly pine (from Forest Service Bul. 64, by R. Zon) may be somewhat increased under careful management. The yield here quoted shows less than the preceding white-pine yield, due to the greater number of white pines per acre. Loblolly pine outstrips white pine in rate of growth for single trees, and in proper situations will receive strong support by southern foresters.

TABLE 9.—*Paper birch in Maine.*[a]

Age.	Mean diameter.	Mean height.	Acre yield.		
			Quantity.		6-inch diameter and over.
	Inches.	*Feet.*	*Cubic feet.*	*Cords.*	*Per cent.*
30 years	5.6	48	1,700	19	46
40 years	7.2	58	2,520	28	75
50 years	8.4	65	3,340	37	91
60 years	9.2	70	3,940	43	98
70 years	10.0	74	4,450	49	100

[a] Data collected by R. Marston.

The table for paper birch represents a woods classification of Quality I and may be a trifle high for average well-stocked, pure birch woods. The table will be of peculiar interest to spool makers. In applying it to large areas of natural forests a large deduction must be made for deficient stocking—again rather showing the possibilities of forest management.

TABLE 10.—*Second-growth yellow poplar—Quality II—Fairfax County, Va.*[a]

Age.	Trees per acre, 5 inches and over.	Mean diameter.	Mean height.	Acre yield.		
				Trees 5 inches and over.		Trees 7 inches and over (Scribner scale).
	Number.	*Inches.*	*Feet.*	*Cubic feet.*	*Cords.*	*Board ft.*
30 years	290	7.8	60	2,750	30	5,800
40 years	255	9.0	65	3,625	40	9,650
50 years	210	10.4	70	4,100	46	11,900
60 years	165	12.0	75	4,575	51	14,200

[a] Data collected by W. W. Ashe.

The mean diameter given above for dense stands is frequently exceeded in less crowded forests, though the acre yield shows the possibilities of the species under systematic management. This species should be of considerable value to southern pulp manufacturers.

TABLE 11.—*Mixed hard-wood coppice, Stewart and Decatur counties, Tenn.*

[White and black oaks about equal in quantity.]

Age.	Trees per acre.	Acre yield.[a]
	Number.	*Cubic feet.*
30 years	700	1,705
40 years	500	1,980
50 years	355	2,160
60 years	255	2,270
70 years	180	2,370

[a] Table prepared under direction of R. Zon.

The mixed hard woods of the southern Appalachians show a better uniform reproduction than the northern pines and spruce and far better than the southern pines, since reproduction results largely from sprouts, and one or two fires will not have the serious effect of preventing all reproduction, though fires do decrease the vitality of the forest and sometimes occur frequently enough to produce barren areas.

20 years	5,275	58	....	....
30 years	7,175	80	....	....

This species, imported from Australia, unfortunately can not be included among our important forest species, since it is confined to almost frostless regions. With its enormous and almost unheard of wood production it is playing an important role as wind-breaks and in the production of fuel in southern California, and may also furnish piles, implement wood, and other materials as it becomes better known. The yields quoted are exceeded by 50 per cent under most favorable conditions.

PRESENT AVERAGE PRODUCTION PER ACRE AND TOTAL PRODUCTION.

From the foregoing notes on the growth of the different species and the yield per acre in the infrequent fully stocked stands of second growth forest, little information can be gotten on the actual wood production throughout our forests, since growth conditions are often very unfavorable. In very old mature forests growth is offset by decay, and our millions of acres of this type of forest may for all practical purposes be regarded as nonproducing capital. Were all our forests of this class, the production per acre would be zero. Were all mature trees removed and the land all densely stocked with thrifty growth, the yield would approximate from 30 to 110 cubic feet per acre per year according to the species and locality. The actual forest represents all degrees of production between these two extremes. There are large bodies of overmature timber that are not increasing. There are small areas of pure second growth producing the maximum amount. There are culled-over areas containing mature defective trees or undesirable species mixed with second growth, areas denuded by ax and fire with no appreciable growth, and, the largest class of all, cut over and burned over lands with some growing trees, but usually not nearly as dense as the virgin forest.

To arrive at any approximation, then, of the total wood production of the country some rough classification of the entire forest area is necessary. Hence the following is offered:

TABLE 13.—*Classification of forest land.*

Region.	Total forest and woodland area.	Probably mature timber and woods.		Probably not restocking.		Probably growing forest and woodland.	
	Acres.	*Per cent.*	*Acres.*	*Per cent.*	*Acres.*	*Per cent.*	*Acres.*
Lake States	47,000,000	4	2,000,000	38	18,000,000	58	27,000,000
Northeastern States	48,000,000	4	2,000,000	18	8,000,000	78	38,000,000
Central States	71,000,000	9	6,000,000	15	11,000,000	76	54,000,000
Southern States:							
Pine land (60 per cent)	124,000,000	33	41,000,000	27	33,000,000	40	50,000,000
Hard wood land (40 per cent)	82,000,000	43	35,000,000	7	6,000,000	50	41,000,000
Rocky Mountain States	97,000,000	70	68,000,000	12	12,000,000	18	17,000,000
Pacific Coast States	76,000,000	80	61,000,000	3	2,000,000	17	13,000,000
Total	545,000,000	....	215,000,000	....	90,000,000	....	240,000,000

The Lake States include Minnesota, Wisconsin, and Michigan; the Northeastern States include Maine, Vermont, New Hampshire, Massachusetts, Connecticut, Rhode Island, New York, New Jersey, and Pennsylvania; the Central States include West Virginia, Ohio, Indiana, Illinois, Kentucky, Tennessee, Iowa, North Dakota, South Dakota, Nebraska, Kansas, and Missouri; the Southern States include Maryland, Delaware, Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Arkansas, Texas, and Oklahoma; the Rocky Mountain States include Montana, Idaho, Utah, Wyoming, Colorado, Nevada, Arizona, and New Mexico; the Pacific Coast States include Washington, Oregon, and California.

The total forest area, including woodland, is seen to amount to approximately 545,000,000 acres, of which about 50,000,000 acres are scrubby woodland, producing only cord wood. This is confined largely to the Southwest, such as the scrub oak, piñon, and juniper lands of California, New Mexico, Arizona, Texas, and other Rocky Mountain States. This estimate of total forest area is based on almost complete returns from county clerks, usually supporting estimates previously made by the United States Geological Survey for Washington and Oregon, the Forest Service forest maps of California and New Hampshire, and the more general state estimates of Doctor Fernow.

The classification into mature timber and cut and burned land probably not restocking are estimates based on reports of Professor Roth for Michigan and Wisconsin and General Andrews for Minnesota, the Geological Survey revised township estimate for Washington and Oregon, by Henry Gannett, together with special reports of state foresters, and more general regional reports, such as the "Report of the Secretary of Agriculture on the White Mountains and Southern Appalachian Watersheds, 1908;" "Southern Appalachian Forests," Ayers and Ashe, Geological Survey; "Timber Pines of the Southern United States," Forest Service Bulletin 13, by Roth, etc. That some difference of opinion may be expressed on this classification is not to be doubted, but the totals are good, errors in high and low estimates compensating to some degree.

The mature timber totals over 188,000,000 acres, which might be raised to approximately 215,000,000 if all woodland such as the scub oak, juniper, and piñon lands of the Southwest is included. It is evident that there is little mature timber in the Lake and Northeastern States. The States included as Central States have a little more mature timber, though culled forests, which consist largely of mature trees, are here included under growing forests to be conservative. The Southern States are figured as having one-third mature timber on pine lands and a little larger proportion of the hard woods of the alluvial bottoms and southern Appalachians. The Rocky Mountain and Pacific coast forests are largely mature forests. Since there has been a great lumber output on the coast it might be supposed that the Rocky Mountain region should have a larger percentage of mature forest, but the thinner forest of the Rockies and much greater damage from fire have tended to lessen the mature forest percentage and greatly increase the "not restocking" percentage. This large area of mature forest can not be considered as increasing materially by growth above the loss by decay, windfalls, insects, etc. The burned areas restocking are included under growing forest.

Under the head of "Probably not restocking" the Lake States lead with 38 per cent. This is due perhaps to the more complete reports and forest and logging conditions which invited the many great conflagrations credited to this region. The larger amount of hard wood, different topography, denser population, larger percentage in small wood lots, and other factors decrease the percentage of forest not restocking for the Northeastern States. These same factors—notably the composition of the forest as of hard woods almost entirely with sprout reproduction—lessen it still more for the Central States. In the Southern States on the pine lands it rises sharply and would be still higher were not the effects of fires less destructive in the more open mature forests still existing. Southern hard woods suffer much less. This is due to their location in the lowlands and mountains, to the less inflammability of nonresinous wood, and to sprout reproduction. In proportion to the cut-over land the Rocky Mountains show a large percentage of land not restocking, while the Pacific coast climatic conditions make reseeding better and safer. The areas of land not restocking are believed to be very conservative even though the total seems startling when placed at about 82,000,000 acres of forest land or 90,000,000 acres of forest and woodland. To the observant forester several trips through the Lake State pineries and southern pineries (where one-half of this land is to be found) are sufficiently convincing. This is the second large item which must be withdrawn from the total so-called forest area. The question may be raised whether this has not already been excluded in the classification of total forest and woodland. It is not, because it is inseparably mingled with the mature and growing timber areas, and it is still potential forest land but unable to restock on account of recurring fires and lack of seed trees. For example, Minnesota is given 15,000,000 acres of forest land, only 7,500,000 of which is restocking to a degree indicative of a second crop. The other 7,500,000, while not entirely devoid of tree growth, will require many decades of efficient fire protection and a large amount of artificial regeneration to bring it into the producing forest class.

The growing forest area is gotten by deducting the mature forest and the area not restocking from the total forest area. This is approximately 225,000,000 acres of forest land, or 240,000,000 acres of forest and woodland. These figures give a total forest area of about 495,000,000 acres, which is raised to 545,000,000 to include woodlands (lands incapable of producing saw timber forest).

Having thus analyzed the total forest area and secured an approximation for the area of growing or producing forest, there remains a discussion of the actual increment on this area. Since (as has been stated before) the growing forest is made up of all conditions of growth from the lightly culled mature forests producing little increment to the pure dense stands of young growth with an increment approaching the maximum, the arriving at an average production is very difficult. The most important single factor is the amount of growing stock present or the density. The second is the age of the growing stock.

In the first column of the table below, the annual production per acre of fully stocked forest is taken as the basis for calculation (being the average for the life of the trees to maturity for all qualities of forest). This is expressed in cubic feet of stem volume (not all of which is merchantable) gotten from the few American yield tables (see Appendix) supplemented by German yield tables, and weighted roughly according to the species in the growing forests of each region.

TABLE 14.—*Estimated growth per acre.*

Region.	Average estimated production in fully stocked forest per acre per year.	Average "best virgin forest" density in per cent of fully stocked.	Estimated density of immature forest compared with best virgin.	Probable growth per acre in growing forest.
	Cubic feet.	*Per cent.*	*Per cent.*	*Cubic feet.*
Lake States	90	60	70	38
Northeastern States	80	60	70	33
Central States	60	70	60	25
Southern States:				
Pine land	70	46	65	21
Hard-wood land	70	70	60	29
Rocky Mountain States	30	58	60	9
Pacific coast States	110	73	70	56

In order to see how the density of our virgin forests compares with the fully stocked forests of the yield tables recourse is taken to a comparison of basal areas (area of tree cross sections). The total basal area (see Appendix) for northern virgin forests containing a large percentage of conifers ranges from 75 to 200 square feet, averaging about 120; the central hard-wood forests from 90 to 150, averaging about 117 square feet; the southern pine forests 30 to 120, averaging 70 square feet; the Rocky Mountain forests 30 to 130, averaging 80 square feet; and the Pacific coast forests 190 to 240, averaging 220 square feet. These basal areas, when compared with Quality II 80-year white pine in New England (see Appendix for normal yield table basal areas and increments), with 242 square feet per acre; paper birch, Quality I, 60 years, in New England, with 120 square feet; loblolly pine in Texas, at 40 years, with 126 square feet; second-growth hard woods in the Southern Appalachians, with 140 square feet; Norway spruce 120 years old, in Germany, with 288 square feet; beech with 192 square feet; and Scotch pine with 212 square feet, show that our virgin forests, even of the best grades as selected and of much greater age than the normal forests compared, are not nearly normally stocked—the redwoods of California being exceptional. This deficiency of stocking in the best virgin forest is expressed by a percentage in column 2 of the above table. Column 3 gives the estimated relation between the immature or growing forest and the best virgin tracts. Here the percentage for the central and southern hard woods is placed at 60, in order to allow for the large number of mature trees still in these culled forests. The density, including these mature nonproducing trees, would of course be much higher than 60 per cent of the virgin forest density.

By multiplying the production in the fully stocked forest (Table 14) by the percentages of effective stocking in virgin and growing forests successively, the last column of that table is secured, indicating a production of from 21 to 56 cubic feet per acre per year in the immature forest in all regions except the Rocky Mountain region, where the large area of juniper, piñon, and scrub oak woodland included in the total wooded area reduces an already low average growth to approximately 9 cubic feet. These figures are believed to be, if anything, higher than the truth.

Applying this estimated average growth to the area of growing forest—

TABLE 15.

Region.	Probable area of growing forest and woodland.	Estimated growth per acre.	Estimated total production.
	Acres.	*Cubic feet.*	*Cubic feet.*
Lake States	27,000,000	38	1,026,000,000
Northeastern States	38,000,000	33	1,254,000,000
Central States	54,000,000	25	1,350,000,000
Southern States:			
Pine land	50,000,000	21	1,050,000,000
Hard-wood land	41,000,000	29	1,189,000,000
Rocky Mountain States	17,000,000	9	153,000,000
Pacific coast States	13,000,000	56	728,000,000
Total	240,000,000	[a]28	6,750,000,000

[a] Average.

an estimated total production of about 6,700,000,000 cubic feet is indicated. This is an average of about 28 cubic feet per acre for the estimated 240,000,000 acres of growing forest and woodland, or about 12 cubic feet for the entire forest and woodland area of 545,000,000 acres, including mature and devastated forests.

Of this probable total of 6,700,000,000 cubic feet the part suitable for saw timber would represent an actual mill output of probably much less than 20,000,000,000 board feet, the rest being cord wood and mill waste.

60 years	7.6	61	2,810	94	5
65 years	7.9	64	3,060	97	5
70 years	8.2	66	3,300	100	2

NOTE.—These sample plots were taken in unmanaged stands. All plots with a density less than 50 per cent were discarded. All plots containing less than 40 per cent birch were discarded, and the remainder reduced to 100 per cent birch by dividing the actual birch yield by the percentages of the total basal area formed by the birch. Hence the table applies only to pure birch stands of average density (Quality I, 83 per cent, and Quality II, 75 per cent). For the yield of a mixed stand containing, for example, 60 per cent of birch, a corresponding reduction would be made in the yield. The number of trees per acre was exceedingly irregular and was therefore excluded from the table.

The volume given is total stem volume, though the lowest measurement taken in the sample trees was at 4.5 feet, and this disregard for butt swelling makes the yield conservative.

[a] Approximate yield in pure, unmanaged, fully stocked stands on old fields.

[b] Round or "waney" edged boards—saw cut. Square-edged material would show a smaller yield.

NOTE.—This table is based on sample plots of limited area. Extended areas could hardly be counted on for such a uniformly dense stand unless openings were carefully planted up and the forest kept under scientific control. On the other hand, the natural stands contained about 10 per cent of other species, which are left out of the total as a factor of safety.

The yields were approximated by means of white-pine volume tables, and 10 per cent was deducted from the yield in box boards against a possible variation between the volumes of bark in the two species and as a further factor of safety.

METHODS OF INCREASING FOREST PRODUCTIVITY.

By E. E. Carter,
United States Forest Service.

INTRODUCTION.

Proper management of any forest necessitates complete protection from fire, and a market in which wood material of both large and small sizes is salable at a price sufficient to make the practice of intensive forestry profitable. Both of these conditions will prevail in this country in the future. Therefore, they are assumed in this paper.

Productiveness will be treated as the equivalent of growth. In a properly managed forest the cut is equal to the growth or increase in wood material, and therefore for such a forest productiveness means both growth and the amount cut. In our forests the cut exceeds the present growth, or production of wood by the forest, for we are now cutting annually the growth of many past years. In the near future the cut can not increase except as the increase in growth or productiveness of our forests makes it possible.

Increase in both the quantity and the quality of the product of our forests can be secured through proper management. The increase in quantity will result from an increased area of absolute forest land being made producing forest, and from having this area stocked with those species of trees which produce in the shortest time the classes of material desired in this country. The increase in quality will result from managing these stands so that material of desirable size and shape is produced.

QUANTITY OF PRODUCTION.

INCREASED AREA.

PRODUCTION FROM FORESTS NOW VIRGIN OR MATURE.

When settlement began the forests of the United States were not producing forests, nor are the yet uncut and unburned areas producing to-day. There are growing trees in all our mature or virgin forests, but their growth is merely enough to offset loss from natural causes, such as decay, windfall, lightning, and insects. The forest has produced and is now merely keeping the amount of its crop at the point reached years, perhaps centuries, ago. It is forest ready for cutting and can be made producing forest only by cutting in a way that will encourage a new crop to grow.

Ultimately the present virgin or mature forests will be cut over, and the land used either for agricultural crops or for new crops of timber. Under proper management the present condition of unproductiveness will never occur again, for the timber crop on any area kept in forest will be cut as soon as, and usually before, it has stopped increasing. The ideal toward which the forester aims in securing this result may be illustrated by assuming that 100 years are required for a timber crop to become mature; that an area of 100,000 acres is to be handled as one forest, and that each cutting is followed immediately by reproduction. The forest would then be divided into a series of one hundred stands, each of 1,000 acres, differing in age by one year, from the yearling trees up to the century old mature timber. Each year the stand which has reached the century mark would be cut, and the crop from that stand of 1,000 acres would be equivalent to the growth for that year on the whole tract of 100,000 acres. Thus the whole forest would be continuously productive.

In our virgin forests it is as if each stand on reaching the age of 100 years had remained stationary until the whole forest is composed of mature timber. There is no increase in the amount of timber on the ground and consequently no productiveness.

It is unnecessary that this virgin forest be cut clean in order to become productive. The removal of the mature timber will give an opportunity for the younger trees already present to grow to maturity, and thus the area will be made productive. In fact, after the cutting of the mature trees which have overtopped them, the young trees will respond to the increase of light, and, in more dry portions of the country, to the increased soil moisture available for them, and they will make more rapid growth than if the forest had been left untouched. Where clean cutting and the establishment of the new crop by artificial means are practicable, or the cutting of mature timber and the leaving of a sufficient number of young trees to insure a full second crop, the area so cut over becomes once more productive.

There are approximately 188,000,000 acres of mature forest, exclusive of woodland, in the United States, not one acre of which can be classed as producing forest. Some of this land is more valuable for agricultural crops than for growing timber, and will be put under cultivation as soon as cleared. A conservative estimate, however, is that 135,000,000 acres of the present virgin or mature forest are more valuable for growing forest crops than for any other purpose, and will become productive forest land.

PRODUCTION FROM WASTE LANDS.

There is in the United States another class of lands which has no productiveness at present. Worn out agricultural soils, cut and burned areas which are not restocking, and sand dunes, are examples of what are commonly called "waste lands." Experiments have shown that some of these areas need only protection from fire to become productive. Any of them can be artificially stocked with forest trees, and so made productive, for forests can grow on soils too poor for successful agriculture, and, as a rule, should be allowed to grow only on such soils. Also, it is extremely probable that future experiments will show it practicable to grow forests on land too dry, too acid, or too alkaline for farming.

There are 81,000,000 acres of forest land, exclusive of woodland, which have been cut or burned over, but are not restocking. Possibly 10,000,000 acres can be used for agriculture, but additions from worn out agricultural soils, sand dunes, and other sources give a total of at least 90,000,000 acres of waste lands in the United States, all of which can be made productive by artificial stocking with forest trees, or in some cases by merely giving protection from fire.

In making this estimate no consideration has been given to the increasingly large areas of plantations on soils which might be classed as agricultural, but which are devoted to tree production for the sake of windbreaks, or farm woodlots. These are not waste lands, but may be classed with them, for they are areas which are not now, but in the future will be, productive forest. They are, however, not considered, in order to make the estimate of 90,000,000 acres the more conservative.

INCREASED AREA FROM SECURING FULLY STOCKED STANDS.

In the United States it is the exceptional forest, even among those which are now producing, which is fully utilizing the area on which it occurs. Lack of care at the time of lumbering and failure to take steps to secure a fully stocked stand give openings in the forest, some of which are occupied by underbrush.

Many of our forests are naturally somewhat open on account of the inability of certain species to endure the slightest crowding by their neighbors. For example, in an old forest of longleaf pine the crowns of the trees cover hardly more than half of the ground, and yet the stand may be fully stocked in the sense that all the trees of that species which can be produced on the area are already growing on it. It is not such lack of density that is considered here, but rather the failure to have the ground occupied as fully as is possible by the species best adapted to the site conditions.

The examples of this lack of density can be found in every part of the country. On the Pacific coast cut-over areas are frequently stocked with a very scattering stand of trees with a dense cover of chaparral or other brush over most of the ground. This underbrush is not only unproductive, but prevents the forest from becoming more dense, since seedlings are unable to start under its shade or to secure the moisture necessary for their existence in competition with the roots of the brush. In the Rocky Mountain region the yellow-pine forests are almost invariably badly understocked as a result of fire or excessive grazing. In eastern Pennsylvania and other middle Atlantic States there are large areas bearing only a very scattering stand of pitch pine and hard woods, while most of the ground is covered with scrub oak and other worthless underbrush.

There are some exceptions to this lack of density. For instance, there are areas of second growth white pine in New England, second growth Douglas fir in the Northwest, or redwood sprouts in California which are fully stocked. It has been shown, however, that taking averages by forest regions, our second-growth lands have only 30 to 51 per cent of the stand necessary to make a fully stocked forest. It is, therefore, safe to assume that at least 80 per cent of our present producing forest of 225,000,000 acres is stocked with only 50 per cent of the trees which should be growing in it, or that our present growing forest could grow on 145,000,000 acres.

Under proper management all of this land will be fully stocked. The vacancies in our present producing forests are, therefore, equivalent to an area of over 80,000,000 acres. If the 135,000,000 acres of unproductive virgin or mature forest and the 90,000,000 acres of unproductive waste lands are added, the total possible increase in area of productive forests is found to be 305,000,000 acres.

INCREASED GROWTH.

RETENTION OF FAST-GROWING SPECIES ONLY.

Some of our native species are among the fastest growing found in the Temperate Zone. White pine and Douglas fir are being used to a large extent in European forests because their growth equals or exceeds that of any native European species. However, there are about 500 species of trees native to the United States, many of which are very slow growing or fail to attain useful size. The wood of others is of very little use on account of poor mechanical properties. It is certain that under proper management these "weed trees and runts," as Doctor Fernow calls them, will be practically eliminated from our forests. Probably not over 70 species will be purposely retained on account of their value for producing wood material.[a]

In determining what trees shall remain in our forests, one of the chief considerations will be the rate of growth, and this will be considered by stands rather than by individual trees.

If production is considered on the basis of weight rather than volume, for the present, it is obvious that stands of species, which fully utilize the influences which cause tree growth, will have a larger production than those which only partially utilize these same resources. Consequently on any site a species, or mixture of species, which forms a complete cover and thus utilizes the sunlight more completely will have a greater production than a species or mixture which, from the inability of the trees to stand shading, must have open spaces between the trees which allows a portion of the sunlight to reach the ground. For example, a forest of spruce will have a far greater weight production than a forest of paper birch, for the former shades the ground so completely that there is usually no underbrush or grass, and the energy from the sun's heat and light is almost completely utilized by the spruce, while with the paper birch only a portion of the sunlight energy is used by the trees, and the remainder reaches the ground where it enables the cover of grass or brush to exist. In his "Economics of Forestry," page 158, Doctor Fernow says: "The intensity of utilization of the light is the important factor in weight production, and ceteris paribus, in volume production." Other characteristics of trees, such as the ability to extract moisture from relatively dry soils, affect the weight production similarly.

Volume production and weight production are not interchangeable, for the specific gravities of our native woods vary greatly, but there are many opportunities for replacing species which grow very slowly in weight and volume, as a result of incomplete utilization of natural resources, or which do not attain useful sizes and form, with species which will grow more rapidly to usable dimensions and form. For example, there are many areas in the eastern United States at present covered with red cedar, a relatively slow growing tree. The cedar could be replaced nearly everywhere by some faster growing species, such as red oak or tulip poplar for the better soils, and white pine or Norway spruce for the poorer. Another illustration of increased yield both in weight and volume is the replacement of gray birch on worn-out fields and pastures in New England by white pine—a process not infrequently occurring naturally. Still another illustration can be made by considering the replacement of hemlock by growing pure stands of white pine, although hemlock probably utilizes the light resources of any site better than white pine, the wood production is low in volume,[a] and its mechanical properties are such that the wood can be used for no purpose for which the more rapidly growing white pine is not suitable. With both gray birch and hemlock the shape and size of the tree render it less valuable than the white pine.

---

[a] Fernow, Econ. of Forestry, p. 169.

This replacement of species by those which grow more rapidly, and the elimination of "weed trees and runts" will be a very long process, and it will be impossible on account of the need for heavy, dense woods to have all of our forests contain only the most rapidly growing species. For example, cottonwood is one of the most rapid growing of our native species, if it is not the leader in volume production. However, white oak, which grows much more slowly in volume but as fast or faster in weight, will be retained on many soils on which cottonwood could grow, because there will always be a demand for wood of the strength and of the mechanical properties which white oak can alone supply.

Furthermore, the wide differences in site conditions in this country will render it necessary to retain some of our relatively slow-growing species, since they are the only ones which can thrive in certain localities. For example, it will probably be impossible to replace our western yellow pine throughout a large part of its range with any faster growing species, for at present no faster growing species is known which will thrive on most sites now occupied by western yellow pine. Similar conditions exist in Europe, as may be shown by quoting from European yield tables for Norway spruce, beech, and Scotch pine on Quality I sites. These show that at 100 years of age the yield of spruce will be 14,248 cubic feet per acre, for beech 8,860 feet per acre, and for Scotch pine 7,760 feet per acre. Although the yield for spruce is nearly double that for Scotch pine, large areas are occupied with the latter species because the site is not suited for growing spruce, but is better suited for Scotch pine than for any other species.

As European foresters have taken some of our species to secure increased growth in their forests, so it will be possible in some instances to increase the yield of our forests by introducing exotics. Norway spruce makes a faster growth than the red spruce of Maine and the Adirondacks, and is now being used in plantations where fire or reckless cutting have made it necessary to replace a spruce stand. The wonderful growth both in weight and volume of eucalyptus in California indicates that this tree is capable of utilizing favorable site factors to a degree far greater than any of our native species, and only its inability to stand frost will prevent its being used to replace our native species over large areas. Unfortunately, its inability to stand low temperatures will result in its being confined almost wholly to areas which are not now forested.

---

[a] The specific gravities of white pine and hemlock are, relatively, as 4 to 5.

INCREASED PRODUCTION OF MIXED STANDS.

The differences between species in their ability to endure shade make it possible, in some instances where soil conditions admit, to grow trees of shade-enduring species under or with species which only partially utilize the sunlight. The method is analogous to the growing of agricultural crops under fruit trees in orchards. To make this possible, it is necessary that the intolerant or light-demanding species be started before the trees of shade-enduring species, or that the intolerant species grow much faster in height. Natural examples of this condition are numerous. On the Pacific coast there is almost always a heavy growth of western hemlock and red cedar under stands of Douglas fir. In the Rocky Mountains Engelmann spruce and white fir are frequently found growing under lodgepole pine when the stands of the latter species are no denser than they should be to secure good growth. In the hardwood region beech and maple are frequently found growing under stands of more intolerant species, such as tulip poplar. Throughout the country, pines and spruces are found coming up on old burns under the aspen which first occupied the ground. Under natural conditions this situation is only temporary, since intolerant species can not reproduce under the shade of the more tolerant species, and consequently the stand in time comes to be composed wholly of the more tolerant trees. Under careful management, however, cuttings will be so arranged that the land is kept constantly producing its maximum amount. In many cases of deliberate mixing of light-demanding, rapidly growing species with shade-enduring, slow-growing species at the time a crop is started, or the underplanting of the crop of light-demanding species, after they have grown to some size, with some shade-enduring species will be practiced. The total growth on an area so treated will be greater than if either species were grown pure, and incidentally the quality of the product is frequently much improved and soil conditions maintained. An experiment in Silesia showed that a mixture of spruce and pine produced 18 per cent more than if the spruce were grown in a pure stand on the same site, or 28 per cent more than if pine alone had been grown.[a] Similar results may be expected in this country from mixtures of carefully selected species, with increases in total production, although, as has been noted, there are large areas within our forests on which desirable mixtures are growing already.[b]

---

[a] Graves, Forest Mensuration, p. 332.

[b] "Only trees which have a fairly full foliage and preserve a good leaf canopy to an advanced age are fit to be raised in pure woods. Species which do not possess these qualities should be mixed with trees of the former kind." Schlich, vol. 1, p. 197 (3d edition).—15.

INCREASED FERTILITY OF WASTE LANDS AND OPENINGS.

The soil on areas which are covered with forest is constantly improving, largely through the beneficial action of the humus or leaf litter. This action is well known to farmers, especially in the South. Frequently forest growth starts on worn-out fields, grows to maturity, is cut, and the soil on the field found to be sufficiently improved to grow good agricultural crops for a few years. The improvement is the same relatively on soils which are kept under forest continuously. Consequently the producing power of the 90,000,000 acres of waste lands in the United States will improve as successive crops of timber are raised on them. The same is true of many areas of our present producing forests, or even some of our mature and virgin forests, which have in the past been burned and have not been under forest a sufficiently long time to reach their maximum fertility. This gain in producing power is, however, slow and varies greatly with species and localities, consequently no figures for it can be given. It is mentioned merely to emphasize the conservatism of the estimates of the increased productiveness possible in our forests.

POSSIBLE AVERAGE PRODUCTION PER ACRE.

The present growth of fully stocked, growing stands ranges from 30 to 110 cubic feet per acre per annum, with an average of 70 cubic feet for the whole country. The actual production per acre is, however, much less, chiefly owing to the absence of fully stocked stands, and when applied to the small proportion of our forest land which is now productive gives a total annual production of only 6,500,000,000 cubic feet.

The estimated growth per acre of fully stocked stands is already higher than for European countries, for our forests as a whole are in regions extremely favorable for tree growth. As an illustration, it may be stated that on over 75 per cent of our forest area the annual rainfall exceeds 35 inches, and in some localities is over 100 inches. Also, large areas of our forests are already covered with fast-growing species, such as white pine, which, on fair (Quality II) sites, shows a mean annual growth at the age of 60 years of over 140 cubic feet, or double the average for the country.[a]

Any attempt to predict an increase in the growth in cubic feet of fully stocked stands for the country must be purely an estimate. Such an increase is certainly possible, however, and a conservative figure for it is 10 cubic feet per acre, making a total annual production of 80 cubic feet per acre.

TOTAL INCREASE IN QUANTITY POSSIBLE.

The possible increase in growth in cubic feet is equivalent to an annual growth of 80 cubic feet on the 135,000,000 acres of our virgin or mature forests, on the 90,000,000 acres of our waste lands, and on the 80,000,000 acres of land unproductive on account of lack of density in our producing forests. This gives a total of 24,400,000,000 cubic feet. To this must be added an increased growth of 10 cubic feet per acre on

---

[a] Present Timber Production, Ziegler, in the report of the conservation commission.

145,000,000 acres (the area on which our present producing forest could be grown), or 1,450,000,000 cubic feet. This makes the total possible increase 25,850,000,000 cubic feet.

QUALITY PRODUCTION.

INCREASED YIELD OF USEFUL MATERIAL.

RETENTION OF NATURALLY WELL-SHAPED AND LARGE GROWING TREES ONLY.

It is not enough that our forests can produce an increased volume of wood. To be truly productive, in the sense of supplying an increased amount of material suitable for use, the wood produced must be of good size and shape. In bringing our forests under proper management not only will slow-growing species be eliminated, but also those which fail to produce stems of a size sufficient to make them capable of use, or of a shape to render possible their use for the objects most desired by the owners of the forests. For example, the redbud of the central hardwood region, although classed as a tree, very rarely attains a size sufficient to make its use possible, and will probably survive only as an ornamental tree in parks and gardens. On the Pacific coast the knobcone pine, even if the poor quality of its wood is disregarded, seldom attains a size sufficient to enable it to be used for saw timber, and consequently it will be especially discriminated against and its reproduction discouraged by foresters. In the Middle West the common catalpa is almost always crooked, and consequently it will be eliminated in time from our forests and replaced, where wood of the same quality is desired, by the straighter growing hardy catalpa. This process of eliminating undesirable species will result in a greater proportion of the total growth of our forests being usable, and will therefore increase the productiveness of our forests.

CONCENTRATION OF GROWTH ON BEST TREES.

Experiments have shown that in a fully stocked stand of any species a definite amount of wood will be grown on a given area each year, or each period of years. Under proper management, the proportion of this growth which will ultimately be used can be greatly increased. If a stand is growing annually at the rate of 80 cubic feet per acre, the proportion of this 80 cubic feet which will ultimately be taken from the forest and used will vary according to whether the wood is placed on stems which have attained or will attain a size suitable for use, or whether it be distributed partly on these stems and partly on trees or branches which will die before reaching a usable size. Therefore, the actual productiveness of the forest can be increased by concentrating as much as possible of the growth on trees which are to remain in the stand until they have attained the most useful size and form.

In this country the benefit of thus concentrating the growth is accentuated by our usual unit of measure of wood products. For practically all saw timber the unit used is the board foot instead of the cubic foot, and timber is sold according to the amount of lumber which can be sawed from the trees. Consequently the larger the tree the greater is the proportion of its actual cubic contents which is paid for and used. It is, therefore, especially desirable to concentrate growth on a relatively small number of trees to force them to large size at the expense of many small trees in the stand.

In the management in fully stocked stands there are always many trees which must soon die from the crowding of their neighbors, consequently their increase in volume is practically wasted. In the meantime they are occupying space and securing light and moisture which could be utilized by the trees which are to remain in the stand, and will be so utilized when the weak trees are finally killed. However, in properly managed stands this process is hastened by the removal of the weak trees, and the growth of the better trees is increased correspondingly. This process is known as thinning.

Examples of the need of thinnings are common in the United States. Lodgepole pine in the Rocky Mountains comes up in exceedingly dense stands on old burns. For a time all the trees grow rapidly, but as soon as the crowns of the trees begin to interlace the struggle for existence begins and natural thinning follows. The growth of the large trees is retarded by the lack of space in which to develop their crowns, and growth in diameter especially soon becomes very slow. The ultimate result in such stands when left to themselves is very frequently that at the age of 150 years there are no trees large enough for saw timber, but many trees of small diameter and good height occupy the ground. If from the start the best trees could have been given an opportunity to develop freely as a result of thinning, there would have been fewer trees to the acre, but these trees would have practically the same volume in cubic contents as the present stand, and would be of sufficient size to furnish a large amount of saw timber. Also, if only fuel wood were desired, a larger proportion of the total cubic contents would be of a size suitable for that purpose.

In this country the demand for saw timber makes the size of the trees on a given area the basis for determining whether the stand is ready for cutting, rather than the total volume of the stand. Since this is so, the concentration of the growth of the comparatively large trees shortens the time required to grow a crop of timber. A crop can be grown, harvested, and a new crop started and grown to some size in the same length of time required for the crop to grow without the aid given by thinnings. For a long period of years, therefore, the productiveness of useful material on any forest area is increased.

Natural thinning is always extremely wasteful, since if the stand is left to thin out itself the trees which die are usually left to rot in the woods. Under proper management this material is utilized and forms from 10 to 50 per cent in volume of the total product of any timber crop.

Throughout the United States it is the exception that more than a small percentage of the material cut from our second growth or producing forests is of sufficient size, shape, and quality to render possible its use as saw timber, ties, poles, or any use other than fuel. The cut of cord wood in this country is approximately 100,000,000 cords a year, the greater portion of which is cut from the forests of the eastern United States. These eastern forests are the ones which have been cut over in the past and are now our productive forests. By far the greater part of our saw timber comes from virgin forests. In cubic measurement the cut of cord wood is greater than that cut for any other purpose. This makes it plain that our producing forests are in reality producing only a very small quantity of saw timber as compared with the fuel wood which they supply.

Proper management by means of thinnings will greatly increase the proportion of large-sized material produced by our forests. Many of our cut-over lands are to-day in practically the same situation as were the forests in parts of Germany at the beginning of the nineteenth century. At that time only 17 per cent of the total amount of timber cut from the forests of Saxony was classed as timber wood. For the period from 1884 to 1893, 79 per cent was timber wood. Similar improvement can be made in our producing forests. At the same time that this increase in the proportion of desirable material was made in Saxony, the annual cut was increased, largely through the use of material removed in thinnings, from 60 cubic feet per acre to 90 cubic feet.

INCREASE IN PROPORTION OF USEFUL MATERIAL POSSIBLE.

If we assume that the total area of our absolute forest land is to be fully stocked with desirable species growing at the rate of 80 cubic feet per annum, the total yield will be 36,000,000,000 cubic feet. Under present conditions, however, an exceedingly conservative estimate would place the proportion of this yield which would be of sufficient size for use as saw timber, ties, poles, or other large-sized products at 25 per cent, or 9,000,000,000 cubic feet. Allowing for waste in logging and milling, this would be equivalent to about 27,000,000,000 board feet. However, by proper care of the forests, the proportion of large-sized material can be raised to at least 50 and possibly to 75 per cent, which would be equivalent to from 54,000,000,000 to 72,000,000,000 board feet per annum; in addition the demand for fuel and other small-sized material would be met by the product of thinnings and the utilization of those parts of the trees which are too small to enable them to be used for saw timber.

SUMMARY.

There are 225,000,000 acres of producing forest in the country. On this area the stand is so open that all the trees could be grown on 145,000,000 acres, which would be producing at the rate of 70 cubic feet per acre annually. By growing only the best species this growth can be increased to 80 cubic feet, an increase of 1,450,000,000 cubic feet.

There is an unutilized area of 80,000,000 acres within our present producing forest. There are 135,000,000 acres of absolute forest land within our virgin or mature forests now unproductive. There are 90,000,000 acres of waste lands which can be made productive by planting or fire protection. All of these areas can be made to produce annually 80 cubic feet per acre, or a total of 24,400,000,000 cubic feet.

The total increase possible in the productiveness of our forests is, therefore, 25,850,000,000 cubic feet.

Only 25 per cent of the yield of our present producing forest is saw timber. It can be made from 50 per cent to 75 per cent saw timber through the concentration of growth on the best trees by thinnings, and the holding of the crop till it reaches good size. This would mean an increase, if all our forest land were productive, from 27,000,000,000 board feet to between 54,000,000,000 and 72,000,000,000 board feet per annum.

FOREIGN SOURCES OF TIMBER SUPPLY.

By Raphael Zon,
United States Forest Service.

Part I.—THE FOREST RESOURCES OF THE WORLD.

SUMMARY.

The United States ranks second among the nations of the world in the extent of its forests. Russia, including Siberia, has the largest forest area of any country, while Canada ranks third.

The forests of the United States, according to ownership, may be divided roughly as follows:

	Acres.
National forests	100,000,000
State forests	3,000,000
Private and unreserved public forests (unclassified)	442,000,000

The proportion of the forest land owned or controlled by the State is not necessarily an indication of the development of forestry in that State. With only a small percentage of the forest area under its ownership, the Government may exercise great control over the forests of all other owners. Thus, for example, Switzerland, Austria, and France, with only 5 to 12 per cent of the total forests under state ownership, practically manage all the forests within their borders. In the United States there is no national or state supervision over private forests.

The proportion of state-owned forests to total forests in the leading forest countries ranges from 2.2 per cent in Great Britain to 31.9 per cent in Germany, and 84 per cent in Spain. In Germany 66 per cent of the total forest area is under state control.

COMPOSITION.

The coniferous species are of the most value in international trade. Coniferous forests produce a larger percentage of structural timber than hardwood forests. The German tendency is to increase the coniferous producing area at the expense of the hardwood area. To some extent this is also necessary, since hardwoods as a rule require better soil than conifers, and the demands for greater agricultural areas relegate the forests to the poorer soils.

In the United States, as the result of the reckless cutting of coniferous forests and of repeated fires, a conversion into hardwood forests and brush areas is going on. This is particularly true in New England, the Catskills, and the Lake States.

In the following countries hardwoods predominate—Australia and Oceania, British India, Hungary, Croatia and Slavonia, France, Japan, Spain, Portugal, Italy, British Isles, Holland, Denmark. In the following conifers predominate—Russia, Finland, Canada, United States, Sweden, Norway, Germany, Austria, Switzerland.

The United States is the only country which has such a variety of conditions as to favor over large areas the growth of a great number of both conifers and broadleaf species.

ANNUAL GROWTH.

The following table classifies the principal wood-producing countries according to whether they overcut, cut the equivalent of the annual growth, or undercut their forests:

	Annual growth per acre.	Annual cut per acre.
Countries which overcut.	*Cubic feet.*	*Cubic feet.*
Austria	42.4	60 to 67 }53
Hungary	44.4	30 to 33
Croatia-Slavonia	43.4	30 to 32
Canada	20.0	[a] 17
Norway	11.3	
Roumania	[b]	[b]
Spain	[b]	[b]
Portugal	[b]	[b]
Greece	[b]	[b]
Turkey	[b]	[b]
Bulgaria	[b]	[b]
United States	12.0	[a] 42.0
Countries which cut just the annual growth.		
Germany	48.7	48.7
France	37.9	37.9
Switzerland	51.0	51.0
United Kingdom	45.5	45.5
Belgium	58.2?	58.2?
Holland	46.0	46.0
Denmark		
Italy	37.3	37.3
Countries which cut less than the growth.		
Russia	31.0	17.0
Finland	19.8	[c] 13.6
Sweden	25.0	19.1
British India		3.0
Japan		35.0
Servia		

[a] Plus great fire loss (estimated 170).

[b] No definite figures on these countries, but facts indicate that they are being overcut.

[c] 3.44 cubic feet in state forests (38.7 per cent); 20 cubic feet in private forests (61.3 per cent).

In most countries where at present the forests are being overcut, and they are the countries which still contain virgin timber, the proportion of structural timber to firewood in the cut is much greater than will be the case in second growth. This is true because the forests under the present system of cutting do not improve but deteriorate in quality. This holds true not only of the United States, but also of Canada, Austria, and Norway. With countries like Germany and France the percentage of saw-log timber is gradually increasing through proper methods of management.

The cut per acre in such countries as Canada, the United States, and Russia does not represent the actual cut per acre, because the figures do not always refer to the actual productive forest area, but include a great deal of unproductive land, such as swamps, burns, etc. If the figures referred only to the productive forest area, if that could be known, the cut per acre would be much higher.

On the whole, the figures of annual cut and growth show a sad state of affairs. Countries which with proper care for their forest resources could continue to be a source of supply of timber to many other countries deficient in wood are, with few exceptions, overcutting their forest and rapidly deteriorating them, and those few countries with large forest resources which do not overcut do it simply because they either lack capital for opening up their forest or natural means of transportation, as rivers, etc. On the other hand, other countries, though they have not enough forests to supply their own needs, continue to deplete what they have.

ANNUAL CONSUMPTION.

The consumption of wood is different in different countries, being dependent on the industrial development, on the presence of coal for fuel, and on substitutes for structural timber. In the following table are brought together the total annual consumption and the consumption per capita in the various countries of the world:

Country.	Total annual consumption.	Consumption per capita.		
		Total.	Timber.	Firewood.
	Cubic feet.	*Cubic feet.*	*Cubic feet.*	*Cubic feet.*
United States	23,000,000,000	260.0	160.0	100.0
Canada	1,111,209,625	192.0	60.0	132.0
Norway	275,000,000	125.0	....	....
Sweden	404,000,000	120.0	....	....
Finland	237,000,000	91.5	....	....
Russian Empire (exclusive of Finland)	6,576,280,000	63.0	25.0	38.0
Austria-Hungary	2,500,000,000	57.0	28.5	28.5
Switzerland	117,000,000	38.0	15.7	22.3
Germany	2,064,122,300	36.6	18.8	17.8
Japan	....	30.0	....	....
France	954,640,000	24.6	6.9	17.7
Denmark	48,826,500	19.8	....	....
Belgium	119,604,126	17.7	10.8	6.9
United Kingdom	670,890,000	14.0	12.8	1.3
Holland	67,200,000	13.1	10.3	2.8
Italy	405,548,000	13.0	2.5	10.5
British India	236,611,600	.8+	....	....

INTRODUCTION.

Under present economic conditions, there is scarcely a civilized country which economically is entirely independent of all other countries. The life of all nations is now closely interwoven; and even countries like the United States or Russia, which contain within their borders practically all natural resources necessary to make them independent in every respect, are constantly interchanging their products with the rest of the world.

It is therefore impossible to form a clear idea of the possibilities of a country and its future development without taking into account the natural resources and the general economic conditions of other countries with which it comes in contact. The highly developed means of transportation makes it often more profitable to obtain certain products from a country which for some reason is best able to produce them than to manufacture them at home, even though it is possible to do so.

A country deprived of certain natural resources may still be prosperous and progressive, because it is able to obtain all that it needs from other countries which have a surplus of the products which it lacks. The British Isles are the most striking example of this. With comparatively limited natural resources and high consumption of timber, grain, and other raw material, England has highly developed industries which enable her to exchange her finished products for the raw materials she needs.[a]

In considering the forest resources of the United States it seems necessary, therefore, to take into account also the forest resources of all other countries in order to determine the extent to which the United States can depend, in case of exhaustion of its own timber, upon the resources of other countries, or to determine the part which it plays and will play in supplying the needs of other countries in forest products.

There is still another reason why it is important in considering the forest resources of the United States to study also the forests and economic conditions of other countries. There is a certain interrelationship between the extent and condition of the natural resources and their use. History clearly shows that in countries with abundant natural resources and sparse population there is no thought of the future, and all energy is directed to the exploitation and reckless use of what nature has abundantly provided. The waste under such conditions is naturally very great and a more economic utilization does not pay. As the population increases and industry grows, the demand for raw material of all kinds increases, and there is a gradual awakening of public opinion to the need of a more careful husbanding of natural resources. Practically all nations have traveled the same road. Some reach this point sooner than others, but every one is inevitably bound to come to the same conclusion. The United States, being younger than European countries and endowed with abundant natural resources, was naturally backward and was until lately lagging somewhat behind. It may therefore be of advantage to this country to seek lessons for our own future guidance in the experience of the older countries which have been benefited by proper care for their forests, waters, and soils.

---

[a] This in a general way holds good for forest resources, but with this difference: Forests not only produce timber, but play an important part in the life of every nation by exercising an influence on the water supplies, on agriculture, and the general health of the people. For this reason only a few countries with an insular climate, as England and Holland, may with impunity reduce their forest areas beyond a certain safety limit. Ordinarily a country with a forest area of 20 per cent or less shows to a marked degree bad climatic conditions, with prolonged droughts, frosts, and alternating floods and low water. Portugal with a forest area of only 3½ per cent of the total land area, Spain with 16 per cent, Greece with 13 per cent, Turkey with 20 per cent, Italy with 14 per cent, are good examples of this.

EUROPEAN COUNTRIES.

The forests of Europe occupy an area of 767,500,000 acres, which is about 31 per cent, or not quite one-third, of the total land area of Europe. The most wooded country is Finland, followed by Bosnia and Herzegovina, and Sweden. The least wooded are Portugal and Great Britain.

In accordance with the proportion of forest to total land area, the countries of Europe may be arranged in the following groups:

	Per cent.
Finland	63
Bosnia and Herzegovina	50
Sweden	47.6
Austria and Russia (exclusive of Finland)	30-39
Bulgaria, Servia, Luxemburg, German Empire, Hungary, Norway, Switzerland, and Turkey	20-29
France, Spain, Belgium, Roumania, and Greece	10-19
Netherlands and Denmark	5-9
Portugal and Great Britain	3-4

The proportion of forests decreases from the north and east of Europe toward the south and west. Russia, Finland, Sweden, and Norway together possess 635,000,000 acres of forest, or 76 per cent of the total forest area of Europe. The following table gives the area now under forest, the percentage of forest area, and the forest area per capita, for most of the European countries:

Extent of forests in European countries.

Country.	Total forest area.	Forest area per capita.	Land area under forest.
	Acres.	*Acres.*	*Per cent.*
European Russia	464,610,600	4.3	36.3
Finland	52,500,000	18.75	54.4
	517,110,600		
Austria	23,926,266	.92	32.5
Hungary	18,692,000	1.17	25.7
Croatia and Slavonia	3,760,000	1.64	35.95
Bosnia and Herzegovina	6,380,000	3.90	50.5
	52,837,266		
Sweden	49,300,325	9.7	48.6
Germany	34,989,672	.61	25.89
France	24,021,587	.61	18.5
Norway	16,848,000	7.00	21.00
Spain	(?)16,065,000	.88	13.00
Italy	10,115,404	.31	14.28
Bulgaria	7,602,815	2.4	30.00
Roumania	6,367,000	1.08	18.00
British Isles	3,030,000	.10	4.00
Switzerland	2,140,012	.67	20.6
Greece	2,023,380	.83	(a)
Belgium	1,303,736	.2	17.7
Portugal	1,236,600	.23	5.0
Denmark	628,575	.25	6.3
Holland	617,567	.1	7.7
Servia	3,864,774	1.55	32.0
	750,192,313		

[a] Less than 13 per cent.

NON-EUROPEAN COUNTRIES.

The forests of other countries of the Old and New Worlds, except in a few localities, are little explored, either as to quantity or quality of the timber. In Asia, Russia, British India, and Japan lead in amount of forests. The following table shows the extent of the forest area in the non-European countries in the Old and New Worlds:

Extent of forests in non-European countries.

Country.	Forest area.	Forest area per capita.	Land area under forest.
	Acres.	*Acres.*	*Per cent.*
Asia:			
Asiatic Russia	348,030,000		
India (Schlich)	149,000,000	0.6	24.0
Ceylon	6,762,880		
Japan	57,718,410		
Philippines	49,000,000		
Malay States	101,560		
Straits Settlements	88,320		
Cyprus	448,000		
Australasia:			
British Australasia	126,720,000		6.4
Java	4,920,000		
Hawaiian Islands	1,224,992		
Africa:			
Cape Colony, Natal, Swazeland, and Transvaal	640,502		
Mauritius	87,680		
Madagascar	25,000,000		19.0
Barbary States	9,526,865		
Central Africa	224,000,000		
South America (tropic)	528,000,000		
West Indies	42,668,800		66.6
North America:			
Canada	799,360,000		38.0
Mexico	25,000,000	1.8	5.1
Alaska	107,000,000		
United States	545,000,000		29.0
Total	3,050,298,009		

As may be seen from this table, the non-European countries possess a forest area of over 3,000,000,000 acres. This with the 750,000,000 acres of European forests, form an enormous total of almost 4,000,000,000 acres, or 24 per cent of the total land area of the world. If to this we add the forests of China, Korea, South America, and Africa, for which there are no available data, the extent of the forests of the world will be still greater. Unfortunately, all figures for forest areas are more or less approximations. While the figures for the forests of Austria-Hungary, Germany, France, Sweden, Norway, Finland, Belgium, and Switzerland are fairly accurate, the figures for Russian, Canadian, or even our own forests are only approximate, and will eventually need correction as our knowledge of the forest resources increases. The enormous forest areas in Russia, the United States, and Canada include a large proportion of unproductive land, such as swamps, burns, or lands which sooner or later will be taken up by agriculture, and which do not therefore give a true idea of the forest land proper. The figures, also, showing the percentage of forest land give only an approximate picture of the distribution of forests in the country, because the proportion of forests to total land area greatly varies in different parts of the same country.

Under "forest" is usually understood to mean land covered with woody growth of economic importance. In prehistoric times, after the Glacial Period and also in the early anthropo-historic times, according to traditions and written documents, forests occupied much larger areas than now. However, there are scientists who hold that some forests—in Europe for instance—were preceded by prairie.

The character of the forest depends upon climate. Forests of cold and moderate regions contain fewer species and are more homogeneous in composition than those in tropical regions. True tropical forests are found in some parts of India and in the basins of the large rivers of South America and Africa. In Java, Borneo, Kongo, and along the Amazon and Oronoco the forests are extremely rich in variety of species.

In the world market the wood of common trees has the greatest economic importance. Pine, spruce, larch, and fir are used for construction purposes; while oak, birch, hickory, etc., are used by wood-working industries. The amount of rare precious woods which are used as articles of international trade is comparatively small.

The different countries of the world may be divided into two groups, according as their wood exports exceed their wood imports, or vice versa.

The countries whose wood exports exceed their imports are: Austria-Hungary, Canada, Sweden, Russia, Finland, the United States of America, Norway, Bosnia-Herzegovina, Roumania, and Japan; the countries whose wood imports exceed their exports are: The United Kingdom, Germany, France, Belgium, Spain, Italy, Holland, Denmark, Switzerland, Australian colonies, British possessions in Africa, China, Greece, West Indies, Bulgaria, and Servia.

This investigation can not be as complete as is desirable because data for many countries are entirely lacking. The facts here given are the best that could be obtained.

In determining the forest resources of European countries it was impossible to obtain any figures which would show the total stand in cubic feet or board measure. In most European forests the cutting of timber is confined either to the annual growth or to a fraction of the annual growth and does not take into consideration the forest capital which produces this growth. The Europeans use the annual growth as the criterion of the present stand.

The forest capital itself, or what we call the present stand, is a constant quantity which is not to be disturbed. With improvement of the forest capital (more fully stocked, faster-growing species, etc.), the annual growth increases and more timber is available for annual cutting.

In this country and Canada, where there are still large areas of mature timber and but little forest management in the strict sense of this word, the present stand in cubic feet or board measure is of special interest, as it shows how much virgin timber is available for cutting and how long it will take to exhaust the supply.

In order to make the results obtained for different countries comparable it was attempted in every case to show the forest area, the annual growth, and annual cut, and from these three factors to make deductions as to the forest resources of the different countries. The topics discussed for each country are as follows: Forest area; distribution of the forest throughout the country; composition and character of the forests; annual consumption, cutting, and growth per acre; and wood prices.

FOREST RESOURCES OF VARIOUS COUNTRIES.

AUSTRIA-HUNGARY.

Austria-Hungary is the greatest wood-exporting country in the world. It is not so rich in forests, however, as Sweden, although some provinces in Austria are very well wooded indeed. The combined forest area of Austria, Hungary, and Croatia and Slavonia, exclusive of the Provinces of Bosnia and Herzegovina, is 46,440,000 acres, or 30.24 per cent of the total land area. The forests of Austria proper, however, are very different from those of the Hungarian Kingdom, and it will be better to consider the two separately.

AUSTRIA.

FOREST AREA.

Forestry has developed differently in various parts of Austria. In the northwest Provinces, such as Bohemia, Moravia, and Silesia, where the population is denser than in any other part of the Empire, the forests were early taken care of. Being close to Germany, these northwest provinces have followed Germany in the management of their forests, and some of them were almost model forests even as early as 1848. In the mountainous parts of the country, however, the conditions are not favorable for carrying on rational forest management, and there it is far from being what it should be.

DISTRIBUTION.

The distribution of forests is very uneven, as may be seen from the following table:

Forest area by provinces.

Province.	Area.	Province.	Area.
Danube Provinces:	*Acres.*	Northwest Provinces:	*Acres.*
Upper Austria	1,684,241.1	Bohemia	3,725,190.0
Lower Austria	1,007,729.1	Moravia	1,507,531.5
		Silesia	430,293.6
	2,691,970.2		5,663,015.1
Alpine Provinces:		Northeast Provinces:	
Salzburg	573,088.5	Galicia	4,829,265.9
Tyrol	2,730,722.4	Bukovina	1,106,854.2
Styria	2,654,118.9		
Carinthia	1,120,104.9		
Cariota	1,093,119.3		5,936,120.1
	8,189,154.0	Total	23,996,266.2
Sea Provinces:			
Gorowitz and Istria	570,345.3		
Dalmatia	945,661.5		
	1,516,006.8		

COMPOSITION OF FORESTS.

The forests are composed principally of conifers, such as spruce, pine, and fir. The coniferous forests occupy 16,868,700 acres, while the hardwood forests of seedling origin occupy only 3,522,400 acres. The hardwood forests contain oak, maple, beech, birch, locust, and alder.

CHARACTER OF FORESTS.

The State owns only 10.7 per cent of the forests, or 2,573,000 acres; of this amount, the actual property of the State is only 1,620,000 acres; the rest is bought by the Government with religious funds in its hands and is under its control. Communes own 14.4 per cent of all forests; hereditary and church forests form 13.6 per cent of the forest area, while in the hands of private owners there are 61.3 per cent of the total forest area. Of the latter, 32.4 per cent are in the hands of large owners, and 28.9 per cent in the hands of small owners. The State takes better care of its forests than does any other owner; then come the forests belonging to churches and large owners. The management of communal forests and of those belonging to small owners is poor.

Austria is a good example of the influence of railroads on the exploitation of forests. Thus, before railroads were built in the forested sections of the country, wood was the only fuel, and saw timber was frequently cut for firewood. With the building of railroads, coal was substituted for wood as fuel, and this brought a change in the utilization of the forests. The consumption of firewood by the city of Vienna may be of interest in this connection. Thus, while on an average for the decade 1848–1857, Vienna, then with a much smaller population than now, consumed each year 200,170 cords, of which 77,841 cords were beech wood; for the decade 1888–1897, the annual consumption of wood fell in Vienna to 51,708 cords, of which only 17,563 cords were beech wood. The price of beech firewood during these two periods was $8.76 and $8.01 per cord, respectively, and of softwoods during the same periods was $5.33 and $7.23 per cord, respectively. This decrease in the consumption of firewood and beech wood was due to increase in the consumption of coal and to the fact that beech in the fifties was rarely used for anything but firewood; therefore, the best beech trees were consumed for this purpose. Now, beech finds employment in many uses, and is in great demand in the manufacture of furniture and other products; only the poorest grades are now cut for firewood.

Of the 23,996,266 acres of forest, 20,390,867 acres are managed as high forest, and 3,605,399 acres as coppice and composite forest.

PRESENT STAND AND ANNUAL GROWTH.

The average yearly growth of all the Austrian forests is given as 1,041,234,000 cubic feet, or 42.4 cubic feet per acre. Timber forms 45 per cent of this annual growth. The forests under different management produce different amounts. High forests produce 42.4 cubic feet per acre, of which 45 per cent is timber; composite forests (coppice with standards), 35.3 cubic feet per acre, of which 20 per cent is timber; and coppice, 32.5 cubic feet per acre, of which only 11 per cent is timber. The least growth is in Dalmatia, where of the total forest area only 7.4 per cent is high forest; and the same is true of Gorowitz and Istria, the other sea provinces. In the Tyrol Mountains the forest is scattered and the annual growth is not large, mainly because large areas are devoted to grazing. The total annual growth in the state forests has been estimated lately at 96,767,000 cubic feet. This, divided by the present area of state forests (which is 2,573,100 acres), gives 37.5 cubic feet per acre. There are, of course, districts where the annual growth in the state forests is as high as 70 cubic feet per acre. Assuming an average rotation of 150 years, the present stand must be somewhere in the neighborhood of 156,000,000,000 cubic feet, or close to 1,000,000,000,000 board feet, or an amount equal to about one-half of the remaining standing timber in the United States. The figure of the present stand must be considered as only roughly approximate. It is here given simply to compare the present stand of the Austrian forests with that of the United States.

ANNUAL CUT.

According to the latest figures, the annual cut in the Austrian forests varies from 1,413,000,000 to 1,580,000,000 cubic feet of wood, which amounts to from 60 to 67 cubic feet per acre. Since the average growth per acre is estimated at 42.4 cubic feet, this would indicate that the forests are being overcut.

HOME CONSUMPTION.

In order to determine the home consumption of Austria, the exports must be deducted from the total cut. Since, however, the export figures are not given for Austria proper, but for Austria-Hungary as a whole, only the home consumption of the entire empire can be calculated. This will be given when discussing the forest resources of Hungary.

The consumption of wood grows every year—not for firewood, as previously, but in the form of ties for railroads and timber for the construction of railroad stations, cars, etc. The consumption for railroads alone is estimated to be over 35,000,000 cubic feet each year. The paper and pulp factories now demand constantly increasing amounts of timber.

WOOD PRICES.

In upper and lower Austria, Styria, and Silesia the following prices per cubic foot prevail; the prices are per cubic foot at the place of cutting in the woods, but include the cost of transportation to the point of shipment along the road:

Average price of soft woods (in logs) per cubic foot.

	Cents.
1848	2.35
1870	4.7
1897	6.33

Average price of cord wood per cord.

	1848.	1870.	1897.
Hard woods	$1.90	$3.27	$4.63
Soft woods	1.42	2.42	3.41

In Bohemia and Moravia the following average prices prevail for timber per cubic foot and for firewood per cord:

	1848.	1870.	1897.
Timber:			
Hard woods (in logs)	$0.068	$0.087	$0.115
Soft woods (in logs)	.034	.054	.08
Firewood:			
Hard woods	2.63	4.20	4.91
Soft woods	2.03	3.06	3.98

In Galicia the wood prices per cubic foot were as follows:

	1870.	1897.
Timber:		
Hard woods (in logs)	$0.033	$0.084
Soft woods (in logs)	.028	.109
Firewood:		
Hard woods	1.56	2.92
Soft woods	1.28	4.00

The figures show that the prices of forest products throughout Austria have increased to a great extent in the last fifty years. However, the price of timber has risen much faster than the price of firewood; thus, while timber prices in many localities have trebled, the price of cord wood has only doubled.

In Galicia the prices of saw logs and cord wood have doubled in the twenty-seven years between 1870 and 1897.

HUNGARY.

FOREST AREA AND COMPOSITION.

According to the latest figures available, the forest area of Hungary is 18,692,000 acres. In this is not included the forests of Croatia and Slavonia, which are a part of Hungary. The forests of Croatia and Slavonia include 3,769,000 acres. Since 1885 the forest area of Hungary, with Croatia and Slavonia, has decreased by 54,000 acres. In the northern part (in the Carpathian Mountains) the forests are chiefly hard woods, consisting of beech (1,463,400 acres), oak (1,374,300 acres), pine and spruce (1,776,600 acres), birch (72,900 acres), poplar and willow (27,000 acres), alder, maple, locust (203,000 acres). The hard-wood forests of the Carpathian Mountains are managed as high forest and yield timber of excellent quality.

Hard woods also predominate in the forests of eastern Hungary. The principal species there are beech (5,891,400 acres), spruce and pine (2,421,300 acres), oak (2,772,900 acres), birch (283,500 acres), willow and poplar (64,500 acres), alder, maple, elm, locust, basswood, and larch (70,200 acres).

In the lowlands are found mainly poplar, willow, oak, locust, beech, in all about 580,500 acres. In the forests of the western part, between the rivers Danube and Drave, hardwoods again prevail. Beech occupies 596,700 acres, oak 866,700 acres, spruce and pine

2,800 acres, willow and poplar 89,800 acres, birch, 86,400 acres, all other species, 72,900 acres.

The areas under different species show clearly that Hungary is principally a hard-wood region, while Austria is principally a coniferous region in which conifers form 82 per cent of the total forest.

Of Hungarian forests 1,182,600 acres are proclaimed as protection forests; 272,100 acres are on shifting sand; 16,889,800 acres are on forest land proper, while 4,220,800 acres are on soil which can not be called absolute forest land.

The forests of Croatia and Slavonia, which form the southern part of Hungary, extend between the rivers Drave and Save, and consist chiefly of hard woods. Coniferous forests occupy only 456,300 acres out of 3,779,500 acres of the total forest area.

Following are the areas occupied by the different species for Hungary and Croatia and Slavonia separately and for the Hungarian Kingdom:

Distribution of forests by States and for Kingdom.

Species.	Hungary.	Croatia and Slavonia.	Hungarian Kingdom.
	Acres.	*Acres.*	*Acres.*
Oak forests	5,200,200	828,000	6,029,000
Beech and other hard woods (except oak)	9,247,500	2,484,000	11,758,500
Coniferous forests	4,217,500	456,300	4,673,700
Total			22,461,200

Thus the Kingdom of Hungary has 26.8 per cent of the total forest area under oak, 52.2 per cent under beech and other hard-wood species, 20.8 per cent under conifers, and 0.2 per cent under brush.

The following areas are managed in the Kingdom as high forest: 3,510,000 acres of oak, 8,367,300 acres of other hard woods, 4,649,400 acres of spruce and pine; the rest, 5,934,600 acres, is in composite and coppice forest, of which 25 per cent is simple coppice.

The forests are distributed according to ownership as follows:

Distribution of ownership by States and for Kingdom.

	Hungary.	Croatia and Slavonia.	Hungarian Kingdom.
	Acres.	*Acres.*	*Acres.*
State forest	2,859,000	724,000	3,583,000
Communal forest	3,745,000	394,000	4,139,000
Church forest	1,207,000	92,000	1,299,000
Private and corporation forest	10,922,000	2,570,000	13,492,000

ANNUAL GROWTH AND PRESENT STAND.

Approximate estimates of the annual growth were made in 1882 and 1894; they do not differ essentially. On an average, one acre of forest in Hungary yielded 44.4 cubic feet, and in Croatia and Slavonia 43.4 cubic feet. The annual yield per acre in coniferous forest was estimated at 58.5 cubic feet, that of oak forest 41.5 cubic feet, and all other forest 40 cubic feet. Experience in the State taught that the different species yielded the following sorts of wood:

	Saw logs.	Cord wood and wood for charcoal.
	Per cent.	*Per cent.*
Oak	25 to 40	75 to 60
Beech	3 to 15	97 to 85
Conifers	70 to 85	30 to 15

These figures show that conifers yield the largest percentage of saw timber, and for this reason Hungary with its hard-wood forests could not export large quantities of structural timber, which must be secured chiefly from Austria. The total annual growth is given as 1,000,000,000 cubic feet. At an average annual growth of about 44 cubic feet and an average rotation of one hundred and fifty years the present stand of timber in the Hungarian Kingdom would be represented by 150,000,000,000 cubic feet, or 900,000,000,000 board feet, or an amount equal to a little less than half the remaining virgin timber in the United States.

ANNUAL CUT.

There are no figures available for the total cut in all the forests of Hungary proper. In the state forests the annual cut per acre is 30 to 33 cubic feet per acre, which is less than the annual growth.

ANNUAL CONSUMPTION.

There are no figures for the annual consumption in Hungary alone, so it will be considered together with Austria for the entire Empire.

WOOD PRICES.

Timber brings fairly good prices. Thus oak, the most valuable of all timber trees, is sold in southern Hungary on the stump at 6½ to 11 cents per cubic foot; in Slavonia, at from 11 to 17½ cents per cubic foot. The market prices of saw timber vary from 44 to 55 cents per cubic foot, and sometimes go even as high as 77 cents. Coniferous wood does not command as high prices and is sold at 3.4 to 6.7 cents per cubic foot on the stump, while the finished product in the lumber yard brings as high as from 16½ to 44 cents per cubic foot.

The prices per cubic foot vary according to the species and the kind of wood, as may be seen from the table below:

Prices of timber and cord wood on stump and in yard.

	On stump.	In lumber yard.
LUMBER.	*Cents.*	*Cents.*
Oak	3.8 to 11.2	9.0 to 13.7
Beech	8.7	11.0
Elm and maple	3.7 to 11.2	7.3 to 13.5
Spruce and pine	1.7 to 6.2	3.8 to 8.4
Larch	2.2 to 8.3	5.0 to 10.0
CORD WOOD.		
Oak	$0.60 to $3.20	$2.07 to $4.02
Beech	$1.31 to $2.60	$2.07 to $4.01

In Croatia and Slavonia the stumpage is given as somewhat higher, especially for oak saw logs and oak staves.

BOSNIA AND HERZEGOVINA.

In considering the forest resources of Austria-Hungary one must mention also the two provinces under the control of Austria, Bosnia and Herzegovina.

The forests of Bosnia and Herzegovina occupy 6,380,000 acres, of which 5,016,660 acres are state forests, and the remaining 1,363,500 acres form private property.

In the state forests 3,572,100 acres are high forest and 1,444,500 acres are coppice. The private forests have 351,000 acres of high forest and 1,012,500 acres of coppice.

The annual cut amounts to 7,487,000 cubic feet of coniferous species, 1,413,000 cubic feet of oak, and 9,006,000 cubic feet of beech, besides a large amount of oak bark for tanning. The exploitation of the forests of Bosnia and Herzegovina is just beginning. Twenty years ago they were hardly used at all.

ANNUAL CUT AND CONSUMPTION FOR THE EMPIRE OF AUSTRIA-HUNGARY.

According to the latest data, the annual cut in all of the forests of Austria-Hungary, including Bosnia and Herzegovina, was 2,827,000,000 cubic feet of wood, or 53 cubic feet per acre. Of this cut one-half was sawed into firewood, the other half made into saw logs, at an average price on the stump of 3.5 cents per cubic foot.

The exports for the period between 1895 and 1899 were, on an average, equal to 320,000,000 cubic feet on the stump. Deducting this 320,000,000 cubic feet from the total cut (2,827,000,000 cubic feet), there remains about 2,500,000,000 cubic feet of wood for home consumption. This, with a population of 43,825,000, would give a consumption of 57 cubic feet to each inhabitant. This consumption was distributed roughly somewhat as follows: 530,000,000 cubic feet were sawed into lumber, 40,000,000 cubic feet were used by the railroads, 30,000,000 cubic feet were consumed by pulp and paper mills, and the rest was used by the people as round timber for construction and fuel. These estimates, though crude, give some idea of the consumption.

CANADA.

FOREST AREA.

The forest area of Canada is estimated as 1,249,000 square miles, or 38 per cent of the total land area of Canada. Not all of this, however, is timber land; only about one-third, or 400,000 square miles, may be taken as covered with merchantable timber, the rest being brush land. According to Mr. Stuart a very large portion of the Dominion forest lands is of little value for commercial purposes. According to his estimates, which are the latest and are authoritative, only one-fifth of the 1,406,200 square miles given by him as more or less wooded area, or 280,000 square miles, can be considered as timber land of commercial value. At an average stand of 2,000 feet b. m. per acre this would give about 360,000,000,000 board feet of mature timber.

According to Mr. George Johnson, the statistical officer of the Dominion of Canada, the area of forests in the different provinces is as follows:

Forest area by provinces.

Provinces.	Area of forest in square miles.	Land area under forest.
		Per cent.
Prince Edward Island	800	40
Nova Scotia	6,500	31
New Brunswick	14,800	53
Ontario	102,100	46
Quebec	116,500	51
Manitoba	25,600	40
British Columbia	285,600	75
Territories	697,100	29
Total	1,249,000	[a] 38

[a] Average.

COMPOSITION.

The Canadian forests are stocked with a large number of species, among which the three most important are white pine, found in the southeast part of the Dominion; spruce, occurring over large areas; and Douglas fir, found principally in British Columbia. Besides these there are a large number of others which play a greater or less part in the lumber trade; as, among the hard woods, ash, birch, elm, maple, beech, oak, hickory, etc. The bulk, however, is coniferous timber, as may be inferred from the fact that of the exports 94 per cent are conifers and only 6 per cent hard woods.

The bulk of the forests is found in the eastern and western provinces, the central part of Canada being occupied by large treeless prairies.

The forests of Canada belong chiefly to the provincial governments and to the railroads. In Manitoba and in the Northwestern Territories the forests are the property of the Dominion government and of Indian tribes.

ANNUAL CUT AND CONSUMPTION.

The total annual cut as given by the census of 1891, amounts to 2,045,073,072 cubic feet, distributed among the different products as follows:

	Quantity.	Cubic feet.
Square timber....tons..	865,696	43,294,800
Logs, masts, and spars....pieces..	48,852,225	407,101,875
Staves....M..	92,260	791,128
Railroad ties and fence poles....pieces..	39,048,162	117,144,486
Telegraph poles....do....	303,861	3,282,175
Fire, lath, and pulpwood and bark....cords..	11,439,541	1,464,061,248
Shingles....M..	939,736	9,397,360
Total....		2,045,073,072

The exports were estimated at 613,000,000 cubic feet, which left 1,431,551,150 cubic feet for home consumption. This made a per capita consumption of 296.2 cubic feet. For the last eighteen years the cut has increased enormously. Professor Fernow estimates the present cut at about 2,400,000,000 cubic feet of finished material, which represents not less than 3,000,000,000 cubic feet as it grows in the forest, or about 17 cubic feet per acre. If to this be added the enormous loss of timber through fire, a loss estimated by some to be equal to nearly ten times the amount cut, the drain is at present probably greater than their productive powers; their exploitation is at the expense of the forest capital itself. There are no figures showing the growth per acre, but it is probably at best not more than 20 cubic feet. Schlich[a] gives the total cut of wood for the year 1900, as given in the census report of 1901, as 1,211,209,625 cubic feet, of which 503,527,545 cubic feet were in the form of timber and 707,682,080 cubic feet firewood. This figure, however, can not be the complete returns for the total cut because it is much smaller than the amount given by the census of 1891; the cut since then has increased.

TIMBER PRICES.

The following table conveys an idea of the prices for the different kinds of wood derived from various species, based on the data obtained in the year 1900:

---

[a] Forest Policy in the British Empire, Vol. I of his Manual of Forestry.

Quantity and value of timber and firewood in 1900.

Class and kind of wood.	Quantity in solid cubic feet.	Value.	Value per cubic foot.
Square, waney, or flat timber:			
Ash	416,308	$43,331.76	$0.104
Birch	1,203,564	147,044.16	.122
Elm	1,354,765	143,020.08	.105
Maple	346,433	35,990.58	.103
Oak	110,219	19,042.04	.172
Pine	2,381,310	445,389.84	.187
All other kinds	5,914,314	605,074.86	.102
Total or average	11,726,913	1,438,861.32	.122
Logs for lumber, etc.:			
Elm	8,224,100	640,421.36	.077
Hickory	165,000	19,153.26	.116
Hemlock	20,077,800	1,094,680.98	.054
Oak	1,042,100	149,605.38	.143
Pine	153,368,100	14,946,604.66	.098
Spruce	104,067,600	7,140,137.04	.068
All other kinds	78,751,600	4,968,582.12	.063
Total or average	365,696,300	28,950,184.80	.079
Miscellaneous timber:			
Wood for pulp	53,442,720	2,107,791.72	.039
Fence posts	33,357,710	564,420.96	.016
Masts and spars	313,880	28,192.86	.089
Piling	2,402,632	228,585.24	.095
Railroad ties	32,607,160	1,367,421.38	.041
Poles for electric wires	2,040,888	202,499.06	.099
Hop and hoop poles	596,074	....	....

Pot and pearl ashes	....	18,676.98	....
		49,652,379.54	

RUSSIA.

FOREST AREA AND DISTRIBUTION.

The forest resources of Russia are enormous. The total forest area has recently been given as 812,640,600 acres, though, as indicated below, this estimate is unquestionably excessive. The proportion of forest to total land area is 15.45 per cent. The forests are very unevenly distributed, however, as is shown by the following table:

Forest area by provinces.

Provinces.	Forest area.	Proportion of forests to total area.
	Acres.	*Per cent.*
Sixty provinces of European Russia	444,711,600	36.31
Caucasus	19,899,000	17.20
Western Siberia	307,530,000	30.39
Eastern Siberia	40,500,000	5.01
Total	812,640,600	25.73

This table does not include the middle Asiatic provinces, as Transbaikal, Amur, and Sakhalin, which comprise 2,316,000,000 acres, and are practically destitute of forests. The proportion of forest for the provinces which have forests is 25.73 per cent, while the proportion of forest to the total area of the empire, without Finland, is only 15.45 per cent. The table also shows how different is the distribution of forests in various parts of the Russian Empire. Thus, while European Russia has over 36 per cent, the Caucasus has only 17 per cent, and eastern Siberia has but 5 per cent of its area under forest. The forests of European Russia are of course of the greatest value. Even there the distribution is very unequal; the five northern provinces contain practically two-thirds of the total forest area.

COMPOSITION.

The composition of the Russian forests is still very little known. In 1893, out of the 315,900,000 acres of forest in European Russia and Caucasus which were under the administration of the forest department, there was 88 per cent of conifers, 11 per cent of hardwood, and 1 per cent of openings and cuttings which did not come up to forest. In Siberia 71 per cent of the total area was under conifers, 29 per cent under hard woods. Oak occupied 3,284,682 acres, either in the form of pure forests or mixed forests in which oak predominated.

OWNERSHIP.

The State owns 640,188,900 acres, or 87.3 per cent of the total area, and only 172,449,000 acres, or 12.7 per cent, belong to other owners. The distribution of the forests according to ownership, however, varies somewhat in the different regions. Of the 444,711,600 acres in European Russia, more than two-thirds belong to the State and Crown, and only 31 per cent to private owners; in the Caucasus the State owns 13,405,500 acres out of a total area of 19,899,000 acres, or 67.3 per cent; in eastern Siberia the State owns about 76 per cent; in western Siberia the State possesses nearly all of the forests; out of 307,530,000 acres, 303,671,700 acres, or 98.7 per cent, belong to the State. Out of 643,067,100 acres of forest belonging to the State there are, properly speaking, only 341,442,000 acres of true forest land, the rest being either agricultural or swamp land. Therefore the total forest area of Russia should be not 812,640,600, but 510,995,500 acres.

Of the total forest area of European Russia, 1,269,000 acres are declared protective forests and 1,225,800 acres are watershed forests. In a similar way, in the Caucasus 81,000 acres are declared protective and 180,900 acres are watershed forests.

ANNUAL GROWTH AND ANNUAL CUT.

A comparison of the annual growth and annual cut per acre in the Russian forests shows that at present only a fraction of the annual growth is actually used. The reason is that the bulk of the forests is located in regions but poorly developed and with no means of transportation. According to the statement of the Russian administration, only a small part of the annual growth can now be used on account of lack of market. The condition in 1898 was as follows:

1. In the state forests of European Russia, over a forest area of 237,500,000 acres, the annual growth was 13.6 cubic feet per acre, of which only 40 per cent, or 5.1 cubic feet per acre could be actually marketed and used.

2. In the state forests of the Caucasus, with 13,250,000 acres of forest, out of a possible yield of 38.4 cubic feet per acre, only 16 per cent, or 6.2 cubic feet per acre, was actually used.

3. In the state forests of western Siberia, with an area of 95,000,000 acres, out of a possible yield of 3.1 cubic feet per acre only 40 per cent, or 1.3 cubic feet, was actually cut and used.

More wood is used in other forests than in those owned by the State, but these amount to only about one-third of the total forest area. In all forests not under control of the Government the cutting is heavier than in those owned by the State. In the following table are given the cut per acre and the total cut in the different kinds of forest:

Annual cut in cubic feet per acre and total cut by ownership.

	Cut per acre.	Total cut.
State forest	5.15	1,249,994,000
Crown forest	10.75	201,267,000
Communal forest	11.15	98,868,000
Peasant forest	18.50	910,406,000
Private forest	37.04	4,554,990,000
Total		7,015,504,000

Thus the annual cut in European Russia is about 7,000,000,000 cubic feet for the productive forest land (412,000,000 acres), or 17 cubic feet per acre. On the other hand, the total annual growth for the same area is estimated at 12,711,000,000 cubic feet, or about 31 cubic feet per acre. In other words, the cutting in these forests is a little more than one-half of what is produced each year.

In the forests of Asiatic Russia the exploitation is practically nil, hardly amounting to 1.3 cubic feet per acre.

CONSUMPTION.

If from the 7,000,000,000 cubic feet annually cut in the forests of European Russia is deducted the annual export of 423,720,000 cubic feet, the remainder is a home consumption of 6,576,280,000 cubic feet. This, with a population of 104,000,000, gives a per capita consumption of 63 cubic feet. Assuming that one-half of the annual growth (12,711,000,000 cubic feet) is saw-log timber, there is produced annually 6,355,500,000 cubic feet of such material. With a home consumption of about 25 cubic feet of saw logs per capita, the total would be 2,600,000,000 cubic feet, which would still leave 3,755,500,000 cubic feet available for export. At present the wood deficit in all European countries together amounts in logs to about 1,412,000,000 cubic feet per annum. This deficit may become three times as large, and still European Russia could apparently furnish enough timber for the countries which depend on importations for their supply.

WOOD PRICES.

In the yearbooks of the Department of the Treasury for 1898 and 1900 are given stumpage prices. Thus, in 1895, in the remote northern government of Archangels, 1 cubic foot of pine timber on the stump was worth 2.7 cents; in 1898, 3.7 cents; in 1895, spruce was selling for 1.9 cents, and in 1898 for 2.1 cents; pine cord wood was worth on the stump 18 cents per cord. In another northern and remote government, Olonezk, timber on the stump was worth 3.5 cents per cubic foot for pine and 2 cents for spruce. In the government of St. Petersburg the stumpage price was 3.7 cents for pine and 2.2 cents for spruce.

In the central governments the stumpage prices were of course much higher. Thus in the government of Moscow the stumpage price for firewood was given in 1898 as $1.60 per cord for pine wood, $1.21 per cord for spruce, $1.16 per cord for oak, $1.70 per cord for birch wood, and 33 cents for all other species; saw-log timber in the same year was worth 6 cents per cubic foot for pine, 3.7 cents for spruce, 2.5 for all other species. In the government of Petrohovsk firewood was selling for $2.31 per cord for pine on the stump, $2.13 per cord for spruce, $3.23 for oak and birch; saw-log timber was selling for 9.8 cents per cubic foot for pine and spruce and 12.3 cents per cubic foot for oak.

These figures give an idea of the range of prices for timber and firewood in the Russian Empire. Stumpage prices have now reached such a point that further advance is hardly to be expected. There are, of course, many places here and there, remote from means of transportation, where forests are still cheap; but as soon as a railroad is built the price of land, and with it the price of timber, will jump at once.

FINLAND.

FOREST AREA.

Finland, although politically part of the Russian Empire, has had an independent economic development.

The forest area may be given as 52,500,000 acres, or 54.4 per cent of the total land area, and 18¾ acres per capita. The State in all owns or controls 32,117,500 acres, or about 61.2 per cent of all the forest area. The rest, 38.8 per cent, belongs to private owners. The forests extend only to the sixty-ninth degree north latitude. Only a few species, like birch, extend farther north. The forests are composed almost exclusively of pine, spruce, birch, and, to some extent, alder. The most valuable species is, of course, the pine, which is, however, of very slow growth. It takes the pine from eighty to two hundred years to reach sizes suitable for construction, and from one hundred and forty to one hundred and eighty years to make saw logs. The farther north it is, the slower, of course, is its growth. As a rule, the spruce occupies more fertile soil than the pine and reaches its development in a much shorter time.

ANNUAL GROWTH AND CUT.

The cut in the state forests for 1897 amounted to 25,737,000 cubic feet, or 0.74 cubic foot per acre. In the northern forests the cut per acre was only 0.43 cubic foot, while in the rest of the forests there was cut as much as 3.44 cubic feet per acre. Of the total cut, 7,837,000 cubic feet formed cord wood.

In the 20,382,500 acres of private forest there was cut approximately 343,000,000 cubic feet each year, or about 17 cubic feet per acre.

The annual growth per acre for all the forests in the country can be considered as about 19.8 cubic feet per acre. From these figures it can be seen that while in the state forests the cut is considerably below the annual growth, in private forests the annual growth is only a trifle more than the cut.

CONSUMPTION.

The total cut in both private and state forests may be estimated at between 369,000,000 and 379,000,000 cubic feet each year. The exports amounted to about from 132,000,000 to 142,000,000 cubic feet, which, deducted from the total cut, would leave about 237,000,000 cubic feet for home consumption, or 91.5 cubic feet per inhabitant.

WOOD PRICES.

The statistical yearbooks of Finland give the prices of finished sawed lumber. Below are the prices for the period between 1886 and 1897, per cubic foot of sawed boards:

	Cents.		Cents.
1886	9.5	1893	12.8
1887	11.1	1894	12.8
1888	9.7	1895	12.2
1890	14.7	1896	12.6
1891	11.8	1897	13.4
1892	12.6		

SWEDEN.

FOREST AREA.

Up to 1897 Sweden was in the lead of all countries exporting timber. In 1898, however, the exports began to lag behind those from Austria-Hungary, which at that time began to increase enormously.

The lumber industry of Sweden is a comparatively young branch of industry which has grown up in perhaps the last forty years. The country is very rich in forests, but the bulk of them lies in the north, which on account of lack of roads is not easily accessible. It is only with the building of railroads that the present exploitation of the northern forests became possible. The driving of logs in the little streams of the north offers great difficulties, but still these streams are used extensively for this purpose in the same way as are those of Maine and northern New York.

The distribution of forests by provinces, the forest area, and the area per capita are shown by the following table:

Forest area and area per capita by provinces.

	Acres.		Per cent of total area under forest.	Forest area per capita in 1898.
	1890.	1898.		
				Acres.
Stockholm	1,011,752.1	1,012,216.5	54.8	2.214
Upsala	607,871.7	692,298.9	54.7	5.562
Sodermanland	691,909.6	715,022.1	46.1	4.32
Ostergotland	1,526,774.4	1,532,152.8	62.2	5.53
Jonkopings	564,129.9	733,549.5	27.9	3.65
Kronobergs	605,915.1	607,999.5	27.6	3.81
Kalmar	882,754.2	1,389,600.9	51.3	6.08
Gotlands	365,261.4	341,188.2	44.3	6.51
Blekinge	281,358.9	280,978.2	39.3	1.92
Kristianstads	486,939.6	507,338.1	33.0	2.32
Malmobus	143,448.3	152,220.6	13.0	.38
Hallands	169 965.0	187,987.5	15.9	1.32
Goteborgs	285,975.9	288,180.9	23.8	.89
Elfsborgs	1,092,833.1	1,328,445.9	45.5	4.75
Skaraborgs	728,546.4	740,545.2	37.1	3.05
Vermlands	3,455,462.7	3,368,970.9	77.7	1.32
Orebro	1,255,362.3	1,276,605.9	62.3	6.62
Vestmanlands	904,502.7	848,650.5	53.1	6.62
Kopparbergs	4,823,784.9	5,133,777.3	73.8	24.09
Gefleborgs	3,556,583.1	3,694,337.1	81.7	16.01
Vesternorrlands	3,926,545.2	4,374,361.8	73.4	19.28
Jemtlands	4,866,169.5	7,259,992.2	61.8	66.34
Vesterbottens	5,414,569.2	5,696,557.2	41.3	40.64
Norrbottens	6,853,885.2	7,227,338.4	29.4	57.59
Total or average	44,592,260.4	49,390,325.1	48.6	9.7

The proportion of forest to total land area, as can be seen, is enormous, being 48.6 per cent. The forest area per capita of population is given as 9.7 acres. This explains why Sweden is capable of carrying on such a large international trade in forest products with the whole world, sending timber even to Australia, Africa, South America, etc. The forest area diminishes from north to south. Its distribution per capita varies in different provinces, in some being as high as 66 acres and in others less than one-half an acre.

In 1890 the state forests comprised 18,058,000 acres; in 1898 the area had increased to 18,641,000 acres. Of this amount the State actually owned 10,063,000 acres, while the remaining 8,578,000 acres were either the joint property of the State and of institutions or were merely under state control. The forest area which is owned jointly by the State and private individuals amounted to 2,295,000 acres. There are more detailed data for the state forests and those under state control than for any other class.

COMPOSITION.

Conifers occupy 80 per cent of the forest area; north of the line from Christiania to Upsala (60° north lat.) is the coniferous region. Birch, aspen, and mountain ash form the uppermost vegetative limit in the northern alpine region. Spruce (*Picea excelsa*) forms the limit of coniferous growth and borders upon the birch region. Pine (*Pinus silvestris*) grows along the rivers. In the central part, pine and spruce occur in pure stands, while along the coast and toward the south they form mixed stands. Oak and beech, in mixture with conifers, are found in the south.

ANNUAL GROWTH AND CUT.

The following table gives an idea of the cut per acre in the state forests and those under state control, for the period from 1889 to 1898:

Annual cut, in cubic feet, in forests under state control.

Year.	Total cut.	Cut per acre.	Year.	Total cut.	Cut per acre.
1889	44,080,000	4.37	1894	46,196,000	4.15
1890	34,906,000	3.15	1895	46,674,000	4.04
1891	39,143,000	3.55	1896	60,374,000	5.19
1892	42,882,000	3.85	1897	67,117,000	5.74
1893	38,647,000	3.48	1898	75,532,000	6.11

As may be seen from these figures, the amount cut per acre grows every year, and it now reaches an average of 6.11 cubic feet per acre. It must be remembered that the state forests are found chiefly in the north, and that of the 8,578,000 acres of state forests in 1890 there were 3,537,000 acres which were swamp land.

The sale of timber in the state forests is either by annual auction sales or otherwise to supply the needs of the local population in fuel, and a small amount of timber for construction, or the timber is sold by contract; the latter method is practiced chiefly in the two most northern provinces.

The average amount of timber, not counting waste, cut each year in all of the forests may be taken as 954,000,000 cubic feet, or 19.1 cubic feet per acre. The annual cut of wood for 1897 was figured roughly as follows: Export of timber (in logs), 246,863,000 cubic feet; export of finished products (except pulp wood), 3,532,000 cubic feet; wood for pulp and paper, 200,845,000 cubic feet; timber for railroads, 50,114,000 cubic feet; and wood for all other purposes, 559,874,000 cubic feet, making a total of 1,061,228,000 cubic feet.

This figure is larger than the one given above (954,000,000 cubic feet) as the annual cut; the difference is due to the fact that in the latter case the amounts were given in the rough, including waste, which in some cases is very great. In the northern parts, where there are no means of transportation, the part of a tree which can not be utilized is often as high as 40 per cent, almost as much as in the United States. In central and southern Sweden, however, the waste does not exceed 5 per cent.

The average annual growth in all the forests is greater than the annual cut per acre. The annual growth has been estimated at 25 cubic feet per acre; therefore the annual cut could be increased to 1,235,500,000 cubic feet without depleting the forests.

CONSUMPTION.

If we add to the amount of timber exported in the form of logs and lumber the amount of pulp wood also, the total exports would amount to 350,000,000 cubic feet. If we deduct this amount from the total annual cut of 954,000,000 cubic feet, the remainder represents a home consumption of 404,000,000 cubic feet, or 120 cubic feet per capita. If we include also the waste involved in the production of the total annual cut, the per capita consumption would probably be as high as 140 cubic feet. K. von Scherzer[a] estimated the consumption in Sweden (in the eighties) at 101 cubic feet per inhabitant. Mulhull[b] gives the consumption in Sweden and Norway as 92 cubic feet per inhabitant. Since these estimates were made the home consumption in Sweden has increased considerably, and 120 cubic feet per capita may be considered as near the truth.

WOOD PRICES.

Unfortunately there are no recent figures for stumpage prices of timber or wood. The latest available figures are for the year 1890. The following table gives the prices of timber on the stump for the whole tree and by the cubic foot:

Prices of saw-log timber.

District.	Maximum price of saw-log timber.		Minimum price of saw-log timber.	
	Per whole tree.	Per cubic foot.	Per whole tree.	Per cubic foot.
		Cents.		*Cents.*
Norbotten	$0.39	1.6	$0.24.2	0.9
Vesterbotten	1.39		.52.0	
Mellerstra Norrland	1.73 to 1.92		0.39 to .52.0	
Gefle-Dala	1.42 to 1.78		.52 to 1.04	
Bergsland	1.35	5.27	.54.0	
Ostra	1.22 to 1.42		.30 to .52.0	
Vestra		2.9		1.72
Smaland	0.52 to 0.78			

In the district of Sodra the oak wood was sold on an average for 2.57 cents per cubic foot. In the district of Vestra cord wood was sold from the woods at 2.75 to 2.87 cents per cubic foot. In 1892 average auction prices for different kinds of wood were as follows:

Auction prices of timber in 1892.

Districts and provinces.	Timber in the square, per cubic foot.	Sawed timber, per cubic foot.	Timber for construction, per cubic foot.	Cord wood, per cord.
	Cents.	*Cents.*	*Cents.*	
Norbotten	2.2 to 4.4	1.0 to 2.3	0.4 to 1.7	$0.18 to $0.36
Vesterbotten	3.7	1.1 to 3.6		.34 to .45
Mellerstra-Norrland	5.1 to 7.3	2.2 to 7.2	.7 to 3.4	
Gefleborg		2.7 to 8.1		.21 to .93
Kopparberg		2.6 to 4.9		.76
Vermland		2.6 to 3.4		3.58
Orebro	2.6	2.9 to 3.6	2.2 to 3.6	1.77
Vestmanland		2.9		1.47
Upsala	2.2	3.6 to 3.9	2.5 to 4.0	1.10 to 1.83
Stockholm		3.2	2.9	1.96
Ostergotland	2.9	3.7	3.2	
Gotland		3.7	3.2	1.96
Skaraborg	2.6 to 3.6	2.6 to 3.6	2.9 to 3.6	1.40 to 4.57
Kalmar	3.6 to 6.0	1.6 to 4.8	4.0	.37 to 3.08
Jonkoping		1.7 to 2.2	1.7	1.85
Kronoberg		1.5		1.36

---

[a] Das wirtschaftliche Leben der Völker, Leipzig, 1885.
[b] Dictionary of Statistics.

The lowest prices for wood were, as would be expected, in the north. In a book[a] published for the Paris Exposition the price of export sawed timber of third quality from 1873 to 1898 was as follows: In 1873, 18.1 cents per cubic foot; in 1874 it was 26.8 cents. After this the price declined, until in 1879 it was only 10.5 cents. In 1883 the price again reached 18.5 cents, in 1897 it was 20.5 cents, and in 1899 it was an even 21 cents per cubic foot. In 1899 and 1900 the price was still high, but in 1901 it fell.

The north of Sweden, the so-called Norrland, is where timber is cut for export. In 1892 the export from Norrland formed 85 per cent of the total export from the Kingdom, and in 1898 was 73 per cent of the total export. With a forest area of 49,390,000 acres, of which probably not less than 10,800,000 acres must be deducted for swamp and is not forest land proper, Sweden has exported on an average for the three years between 1897 and 1899 wood valued at $46,604,500, or at about $1 per acre. Such an export must be considered very large.

The bulk of saw logs is delivered to the harbor by water. There is not a single river in Norrland[b] which is not used for log driving.

One of the greatest scourges in Sweden, as in this country, is forest fires: In 1887, 14,580 acres were thus destroyed, and in 1892, 145,800 acres.

NORWAY.

FOREST AREA.

With a total land area of 124,130 square miles, Norway possesses a forest area of 16,848,000 acres, or 21 per cent of the total land area. The bulk of the forests lies in the northeast, where the proportion of forest is 38 per cent; in the north the forest occupies only 6 per cent of the land area, and in the central part 13 per cent. The forest area per capita is 1.25 acres.

OWNERSHIP.

The state forests comprise 6,807,500 acres, or 28.5 per cent of the forest area. Over one-half of this amount is in the northern provinces of Tromsoe and Finmark, and of this only 1,970,000 acres are really productive forest land. Corporation forests occupy 787,700 acres, or 4.6 per cent; of this, 632,500 acres are productive. Private forests comprise 10,393,250 acres, or 66.9 per cent.

COMPOSITION.

Coniferous forests occupy 75 per cent and hard woods 25 per cent of the total forest area. Among the hard woods beech, elm, and oak, especially the pedunculate oak, predominate. However, the hard woods do not play an important part economically. Beech only forms forests south of Christiania, oak on the southern and eastern coasts up to 63° north latitude, and birch extends beyond the Arctic Circle inland as well as along the coast.

---

[a] La Suède, son Peuple et son Industrie.

[b] L. Passarge. Schweden; Fahrt in Nordschweden und Lappland, Berlin, 1897.

The most common of all trees is the pine. It extends beyond the Arctic Circle to 70° north latitude, and forms the most northern forest in existence. It occurs all over the country. Its vertical range is also higher than that of spruce. It ordinarily reaches maturity at 150 years, but in the mountains and in the north at 200 years. The spruce does not extend beyond the Arctic Circle, and occurs on the western coast only scattering or singly. In the South it can be utilized at an age of from 70 to 80 years; in the rest of the country, between 120 and 150 years.

In Norway the growth extends much farther north than in any other country.

ANNUAL CUT, GROWTH, AND CONSUMPTION.

The annual cut is given as 345,000,000 cubic feet, or 20.4 cubic feet per acre. In the forests south of latitude 65° (15 provinces) the annual growth is estimated at 20.5 cubic feet per acre—indeed, in the southwest, at 22.6 cubic feet; west and south of Tondhjem, at 17.9 cubic feet; north of Tondhjem, at 11.3 cubic feet. The actual utilization in this region, however, amounts to 21.5 cubic feet. The convenient access to the western coast, with its deep, sheltered fjords, caused the depletion of the forests in that region. It is estimated that during the last one hundred and fifty years 15,000 acres of private forests have been cleared each year. These figures indicate that the forests of Norway are now being overcut.

One-fifth of the total cut (69,000,000 cubic feet) is exported, and the rest, 276,000,000 cubic feet, remains for home consumption. This, with a population of 2,240,000, gives a consumption of 125 cubic feet per capita.

The peculiarity of the export is that the bulk is in the form of logs and staves and not of sawed lumber. Thus, in 1895 to 1899 the export of sawed lumber formed only 28 per cent of the total. This is in contrast to Sweden, which exports chiefly sawed lumber.

WOOD PRICES.

There are no available statistics regarding wood prices in Norway. They can not, however, be very different from those in Sweden.

The Norwegians realize that at the present cut and export, which in itself amounts to 83 cents per acre, they are cutting not only the annual growth, but the capital itself, and that therefore the forests can not last very long.

BRITISH INDIA.

FOREST AREA.

The total forest area of British East India is not known. The area of state forests under the management of the forest department is nearly 149,000,000 acres. There are extensive areas of private and village forests, but they hardly play an important part in the timber supply of the country. Since the government is owner of all land, except in places where it relinquished its right of ownership to individuals or charitable institutions, the present area of state forests probably includes the greatest part of all forests. The forest area occupies nearly 24 per cent of the total land area, and represents 0.6

of an acre per inhabitant. The state forests are divided into three classes: Permanent state forests (or reserved forests), protected forests, and unclassed forests.

The reserved forest forms only 9.5 per cent of the total land area. In the following table are given the areas of the different classes of government forests in the various provinces:

Government forests, in square miles, under the control of the forest department June 30, 1903.

Provinces.	Total area.	Reserved.	Protected.	Unclassed.	Total.	Per cent of land area under forest.
Bengal	152,453	6,014	3,567	4,033	13,614	8.9
United provinces of Agra and Oudh	105,165	4,048	30	77	4,155	3.9
Punjab	97,223	2,456	4,909	1,914	9,279	9.5
Burma	162,530	20,039	....	103,174	123,213	75.8
Central provinces and Berar	104,170	22,672	....	4	22,676	21.8
Assam	48,961	3,778	....	18,509	22,287	45.5
Coorg	1,582	410	39	121	570	36.0
Northwest frontier province	13,276	234	....	....	234	1.8
Ajmer	2,646	142	....	6	148	5.6
Baluchistan	9,403	208	....	....	208	2.2
Andamans	3,143	156	....	1,795	1,951	62.1
Totals:						
Bengal Presidency	700,552	60,157	8,545	129,633	198,335	28.3
Madras	144,389	17,923	....	1,636	19,559	13.5
Bombay	122,883	13,487	1,320	....	14,807	12.0
	967,824	91,567	9,865	131,269	232,701	24.0
Grand total (acres)	....	58,602,880	6,313,600	84,012,160	148,928,640	....

COMPOSITION.

The composition of the Indian forests is entirely different from that of the United States or Europe. The forests are almost exclusively hardwood, although some are evergreen and some deciduous. The evergreen forests are found mainly along the west coast of the peninsula, in coast districts of Burma and Chittagong, and along the foot and lower slopes of the eastern Himalayas. The deciduous forests are found in the central part of the peninsula and of Burma and contain the most valuable timber trees, such as teak, sâl, sandalwood, red sanders, ironwood, padouk, and others. Conifers (pine, firs, and deodar) are found at the higher elevations in the Himalayas.

ANNUAL CUT AND GROWTH.

The total cut for 1905-6 amounted to 239,250,000 cubic feet, of which 171,500,000 cubic feet was in the form of fuel. Besides this, there were also cut 210,000,000 bamboos. If this cut be divided by the total forest area, the cut per acre would be extremely small, 1.6 cubic feet; this figure does not really represent the true cut, however, because it is referred to an enormous forest area, of which only a comparatively small portion is actually utilized. When the cut is referred to a definite area, the cut per acre is much larger—for example, in Bengal, in the year 1899-1900, from an area of 5,707,800 acres there were obtained 7,340,000 cubic feet of saw timber, 34,566,000 cubic feet of firewood, and 21,000,000 cubic feet of bamboo, or, in all, about 11 cubic feet per acre, and, not counting the bamboo, only about

8 cubic feet per acre. Therefore, to get a better idea of the cut per acre, the total cut should be divided by the area of reserve forests (58,602,800 acres), which would make about 3 cubic feet per acre, not counting bamboo.

There are no figures for the growth per acre. From a study made on sâl, the growth per acre of sâl coppice was estimated to be nearly 30 cubic feet per acre per year. Therefore it is safe to assume that the annual growth in the Indian forests is at present larger than the annual cut.

CONSUMPTION.

The timber exports consist chiefly of teak wood, of which 52,768 tons, or 2,638,400 cubic feet, were exported in the year 1905–6. The exports of all other kinds of wood, principally of bamboo, are insignificant. If this amount be deducted from the total cut and there were no importations, there would be available 236,611,600 cubic feet for a population of nearly 300,000,000 inhabitants, or 0.8 cubic foot per capita. There are, however, some imports of timber from Canada, Sweden, and Austria, which, on an average for the five years between 1895 and 1900, formed one-eighth the value of the total exports. Of course these imports slightly raise the per capita consumption. Still the consumption and cut are very small, and the fact that saw-log timber is needed from other countries indicates the lack of structural timber.

WOOD PRICES.

The chief timber of export is teak, and its price at the point of shipment varies from about 80 to about 85 cents per cubic foot.

ROUMANIA.

FOREST AREA.

The forests of Roumania comprise 6,367,000 acres, of which the State owns 40 per cent, the Crown and communities 8 per cent, and private individuals 52 per cent. The proportion of forest to land is 18 per cent and the area per capita is a trifle over 1 acre (1.08). Of the land classed as state forests (2,712,500 acres), 1,497,000 acres are utilized, 806,250 acres are not utilized, and 407,500 acres are burned.

COMPOSITION.

Thirteen and one-half per cent of the total forest area is occupied by spruce and fir; 20 per cent by beech (also mixed with conifers); 28.3 per cent by beech, oak, and elm in mixture; 31 per cent by pure oak forests; and 7.2 per cent by other hardwood species. The conifers occur chiefly in the Alps and Carpathian Mountains, where their exploitation is very difficult. Only part of the state forests are now being utilized. The insignificant exploitation is due to lack of capital and enterprise. The Government, in order to strengthen the lumber industry, imposed a duty on timber, which increased its price, reduced its importation, and stimulated export. In the future Roumania will undoubtedly play an important part in supplying other countries with timber.

There are no data for the annual growth or consumption. Figures for the annual cut are extremely meager and unreliable.

JAPAN.

FOREST AREA.

The total forest area of Japan, exclusive of Formosa and the Kurile Islands, is 57,718,410 acres, or 59 per cent of the total area. The forests are more extensive in the northern part and are practically confined to the slopes of the mountains which form the backbone of the islands. The greater part of the forests belong to the State. The following gives the distribution of forests according to ownership:

Distribution of forests by ownership.

	Area in acres.
State forests	32,813,300
Crown forests	5,229,472
Municipal forests	4,286,885
Forests of shrines and temples	419,073
Private forests	14,969,680
Total	57,718,410

The state and crown forests are carefully managed, but the private forests are not in such a high state of perfection. In proportion to population, the forest area is quite different in the various provinces; thus in Hokkaido it is 9 acres per capita; in Aomori and Akita, 3¾ acres; in Kochi, 1 acre; in Hiroshima and Kagoshima, three-fourths of an acre; and in Kumamoto only one-half acre. The northern provinces are still rich in virgin forests.

COMPOSITION.

The forests are divided into four zones: 1. Tropical forest; 2. Subtropical forest; 3. Temperate forest; 4. Frigid forest.

1. The tropical forest zone extends over the whole of Formosa, the southern half of the Soochoo Islands, the Yayemaya, and the Ogasawara Islands. The banyan, sieb, and bamboo are the principal growth.

2. The subtropical forest zone comprises a portion of the Soochoo Islands, the whole of Shikoku and Kyushu, and the part of the main island lying south of 36°.

3. The temperate forest zone extends from the northern half of the main island to the southern part of Hokkaido, between 36° and 43° 5′, where the mean annual temperature ranges from 6° to 13° C.

4. The frigid forest zone occupies those parts of the northern half of Hokkaido and the Kuriles, where the average temperature does not exceed 6° C.

On the whole, the composition of the forests is somewhat as follows:

Conifers, 21 per cent; broadleaf forests, 25 per cent; conifers and broadleaf forests, 45 per cent; and sparsely stocked forests, 9 per cent.

In the state forests, the relative proportions of the different kinds of trees is as follows:

Conifers, 11 per cent; broadleaf forests, 28 per cent; mixed conifer and broadleaf forests, 49 per cent; and sparsely stocked forests or openings, 12 per cent.

ANNUAL CUT, GROWTH, AND CONSUMPTION.

The annual cut of timber for three successive years (1900 to 1902) was on an average 2,055,059,400 cubic feet, or about 35 cubic feet per acre. If Japan were not an exporting country, as it is now, at an annual cut of 2,055,159,400 cubic feet and a population of 43,760,000 (exclusive of Formosa), the annual consumption per capita would be 47 cubic feet. As a matter of fact, exports exceed imports, but the exact amount in cubic feet is not available. The actual per capita consumption in Japan must therefore be less than 47 cubic feet, and an estimated consumption of 30 cubic feet must be close to the truth.

There are no figures of annual growth per acre for the whole country. From some working plans prepared for the different state forests it appears that stands of *Cryptomerea japonica* may produce as much as 130 cubic feet per acre per year, and those of *Thujopsis dolabrata* 100 cubic feet per year. From the fact that the Japanese manage to get excellent agricultural crops it may be inferred that they also know how to husband their forest resources and will be able to supply all of the needs of the population and their wonderfully progressive industries.

WOOD PRICES.

Below is given a table of wood prices at Tokyo for the different Japanese woods used in construction, mining, etc.

Prices and uses of various Japanese woods.

TIMBER.

Species.	Price at Tokyo.[a]	Used for—
Chamaecyparis obtusa.......cubic foot..	$0.40	House, ship, and bridge construction.
Cryptomeria japonica............do....	.25	Do.
Picea ajanensis...................do....	.275	House and ship building.
Larix Leptolepis..................do....	.275	Ship and bridge building, telegraph poles, sleepers.
Pinus densiflora..................do....	.15	Piles, etc.
Thuja Sieboldii...................do....	.175 .20	House building, shingles, pulp.
Fraxinus Mandshurica............do....	.25	House and boat building, ties.
Juglans Sieboldina...............do....	.40	Rifle stocks, furniture, carriages.

BOARDS.

Species.	Price at Tokyo.[a]	Used for—
Cryptomeria japonica ..square foot..	$0.15	Valuable furniture and ornaments.
Thuja japonica....................do....	.05	Shingles, cabinets, etc.
Zelkowa keaki.............cubic foot..	.90	Ship, carriage, and house building.
Acer palmatum...................do....	.40	Implements, wagons, etc.
Fagus sylvatica var. Sieboldi....do....	.125	Boats, sleepers, foundations.
Quercus acuta....................do....	.35	Carriages, machines, implements.
Quercus crispula..................do....	.25	Fuel and sleepers.
Cinnamomum camphora..........do....	.55	Boats, cabinets, camphor.
Magnolia hypoleuca..............do....	.35	Small articles.

[a] Original values are given in yen. 1 yen equals about $0.50 United States gold.

THE UNITED KINGDOM OF GREAT BRITAIN AND IRELAND.

FOREST AREA.

The forests of the United Kingdom occupy but a small proportion of the total land area. The area of woodlands is estimated at

3,030,000 acres, or 4 per cent of the total land area. The following table gives the proportion of land used for different purposes:

Utilization of the land.

Countries.	Acres of dry land.	Acres under crops and grass.	Acres of forests.	Acres of mountain and heath land.	Acres of other lands.
England	32,390,901	24,679,966	1,665,741	2,324,624	3,710,660
Wales	4,748,466	2,810,824	181,610	1,270,470	485,564
Scotland	19,068,958	4,897,109	878,765	9,289,378	4,003,646
Isle of Man and Jersey	185,453	124,650	869	29,729	30,205
Ireland	19,322,798	15,230,501	303,023	2,226,867	1,562,317
Total	75,706,668	47,743,200	3,030,008	15,141,068	9,792,392
Percentage	100	63	4	20	13

The area under forest per capita is one-tenth of an acre. The area of woodland is smaller than that of any other European country except Denmark. Crown forests comprise only some 67,000 acres, or 2¼ per cent, which is smaller than in any other European state. There are no communal forests. Of the total forest area, 97¾ per cent, or 2,963,000 acres, is in the hands of large private owners.

ANNUAL CUT, CONSUMPTION, AND GROWTH.

The total cut in the United Kingdom for certain periods amounted to: 1855–59, 125,703,600 cubic feet;[a] 1875–79, 131,353,200 cubic feet; and 1895–99, 138,062,100 cubic feet.

Thus the average cut per acre may be accepted as equal to 45.5 cubic feet per year. Assuming that in England only the annual increment is cut, the annual growth would be equal to the total cut. Mulhull estimated that the annual growth per acre is equal to 60 cubic feet, in which case the total annual growth would be 181,800,000 cubic feet. The United Kingdom not only uses all that is cut, but is impelled to import nearly five times that amount.

The total annual consumption and the per capita consumption for a period of years are given in the following table:

Annual and per capita consumption, in cubic feet, for certain periods.

Period.	Produced at home.	Imported.	Total.	Per capita.
1855–59	125,703,600	84,037,800	209,741,400	27.2
1875–79	131,353,200	329,442,300	460,795,500	12.0
1895–99	138,062,100	533,181,000	671,243,100	14.0

Thus the per capita consumption is 14 cubic feet. Half of the total annual cut is firewood; therefore the consumption of timber is 602,212,000, and of firewood is 69,031,000 cubic feet; or the per capita consumption of timber is 12.8 cubic feet, and of fuel is 1.2 cubic feet.

---

[a] Berichte über Handlung und Industrie 1900, 598.

WOOD PRICES.

Since the United Kingdom buys nearly half the total export of all the countries of the world, the wood prices in the English market affect practically the whole world. It will, therefore, be of interest to compare the prices for the different kinds of wood imported for a long period of years. The following average annual import prices are borrowed from the Statistical Abstracts for the United Kingdom (1892–1900), covering a period of twenty-four years.

Prices in cents per cubic foot of imported woods.

Year.	Round and hewn logs.			Sawed lumber.	
	Pine and spruce.	Oak.	Teak.	Pine and spruce.	Staves.
1877	22.6	58.8	109.8	....	50.7
1878	19.7	55.6	92.8	....	46.2
1879	17.2	48.7	91.5	....	45.7
1880	19.5	54.4	114.5	....	42.9
1881	19.7	56.4	125.6	....	46.7
1882	20.2	58.2	121.6	25.1	48.9
1883	19.5	57.5	134.4	23.5	42.8
1884	17.4	54.5	137.0	22.1	38.8
1885	16.9	54.1	127.3	21.9	40.8
1886	14.9	53.7	115.1	20.8	38.4
1887	14.0	52.1	98.3	19.8	38.8
1888	15.0	51.1	100.3	21.1	38.7
1889	16.7	54.6	112.8	23.6	38.5
1890	15.4	53.8	106.7	22.2	40.5
1891	14.2	55.6	97.0	20.2	42.8
1892	14.2	55.6	100.9	20.6	41.2
1893	13.2	55.7	97.4	20.2	36.7
1894	12.6	57.0	99.2	20.5	38.7
1895	12.8	54.9	91.4	19.7	38.8
1896	13.4	56.0	100.4	20.8	49.8
1897	13.6	54.3	109.9	22.2	42.4
1898	13.9	53.4	111.2	22.2	43.8
1899	13.7	53.2	114.6	22.8	49.3
1900	14.5	55.9	117.7	26.3	46.9

The lowest price for pine and spruce logs was in 1894. In general, the prices of log timber imported into the United Kingdom were lower in the nineties as compared with the prices that prevailed in the seventies. This may be accounted for by a change in the kind and quantity of logs imported. In the seventies the importations consisted chiefly of large logs, while now the timber imported is generally of smaller size and a great deal of it is for mine timbers and pulp. The prices for logs are comparatively uniform. Teak is used in large quantities for the navy, and its price depends not only on the supply, but also on the demand for it. Lately there has been a great demand for the building of the navy and merchant marine, which has increased the price of teak.

The prices for sawed lumber had fallen greatly by 1895, but since then they have shown a continuous increase. The prices for staves were also low in 1894 and 1895, but lately have shown a tendency to rise.

It is also of interest to compare the prices which different countries have commanded for their timber:

Comparison of selling prices, in cents per cubic foot, of timber in various countries.

	1896.	1897.	1898.	1899.	1900.
Pine and spruce logs from—					
Russia	15.8	16.3	16.9	17.6	18.6
Sweden	13.3	13.8	13.1	14.3	15.7
Norway	13.8	14.3	15.0	15.0	16.6
Germany	20.2	20.8	21.8	24.0	25.2
France	8.1	8.0	8.2	8.2	8.9
United States	28.6	29.2	29.0	32.6	33.2
Canada	55.0	53.0	50.7	54.3	55.0
Pine and spruce sawed timber from—					
Russia	21.9	24.1	24.1	25.0	29.5
Sweden	21.7	23.8	24.0	24.4	27.4
Norway	24.9	27.0	27.1	27.6	28.8
Germany	23.9	25.2	26.3	27.6	35.0
United States	26.4	26.6	26.8	29.2	34.1
Canada	24.4	24.7	24.5	25.1	28.7

The highest prices for hewed as well as unhewed timber were commanded by Canada and the United States, as these countries supplied the largest logs. The timber from Russia contained a great deal of small logs for mines. That from Sweden and Norway was at the lowest prices because it contained very small logs. France ships to England pulpwood only, and such timber is practically on a par with firewood. For sawed lumber, Germany and America commanded the highest prices.

The following tables are of interest as giving details of timber values:

Stumpage prices, in cents per cubic foot, of timber in the south of England, 1904–1905.[a]

	Price.
Prime clean oak, standing	50
Rougher oak	44
Clean-grown ash	60
Beech, 20 inches in diameter and upward	24 to 32
Elm	24
Good clean willow, suitable for cricket bats	60
Hard woods, small dimensions	12 to 18
Larch	24 to 28
Scotch pine and spruce	8 to 16

GERMANY.

FOREST AREA.

According to the latest figures obtained by the census of 1895, the total area now under forest in Germany is 34,989,672 acres. This forms 25.89 per cent of the total land area. The forest area is 0.63 acre per capita. The distribution of the forests in the different States in the German Empire is given in the following table:

Area of forests of German Empire, 1900.

States.	Total area of forests.	Land area under forest.	Area per capita.
	Acres.	*Per cent.*	*Acres.*
Prussia	20,675,335.0	23.7	0.60

German Empire	1.8	31.9	16.1	1.5	2.2	46.5

The forest area has changed comparatively little since 1878. In some parts of the Empire there has been a decrease, but in the country as a whole there has been a steady increase. The following table shows the changes mentioned:

Increase, in acres, in forest area of German Empire.

	Total wooded area.	Increase.
1878	34,682,315.0	....
1883	34,770,995.0	88,680.0
1893	34,892,067.5	121,072.5
1900	34,989,670.0	97,602.5
Total	....	307,355.0

The Government has determined the area that may be converted into forests. This potential forest area has been computed at 1,583,000 acres, or 4½ per cent of the present total forest. Of this, 1,362,500 acres are in Prussia alone, which would increase the present forest area by 6.6 per cent. Prussia is doing a great deal in bringing under forest much of its waste land. Thus from 1867 to 1892, 336,582 acres of waste land were bought at $16 per acre to plant to forest, and from 1883 to 1902, 182,782 acres were brought under forest, or an average of 9,140 acres per year. On October 1, 1903, the Prussian forest administration possessed 91,202 acres of waste land, which it intended to plant with trees.

COMPOSITION.

Of the forests, 32½ per cent are covered with hard woods and 67½ per cent with conifers. The constant tendency is to increase the latter at the expense of the former.

The following figures show the progress made in this dirction:

	Hard woods.	Conifers.
	Acres.	*Acres.*
1883	12,006,450	22,704,545
1893	11,668,025	23,207,800
1900	8,802,000	23,627,673

Thus in 1883 the hard woods occupied 34½ per cent instead of 32½ per cent, and the conifers 65½ per cent instead of the present 67½ per cent. The remainder of the forest, comprising 2,699,997 acres, is a mixed composition of hard wood and conifers. In the following table are given detailed figures of the composition of the forest and the areas under different methods of management:

Percentage of forest composition by States.

ANNUAL CUT.

The total cut as given for the year 1899–1900 is 1,706,431,900 cubic feet of timber, or 48.7 cubic feet per acre. The following tables give a clear idea of the annual cut for the whole Empire, as well as for the different States comprising it:

Yield of wood, 1899–1900.

	Actual amount.	Total cut.	Amount per acre.
	Cubic feet.	*Per cent.*	*Cubic feet.*
Timber (nutzholz) [a]	706,631,729	41.4	20.2
Firewood	630,127,804	36.9	17.9
Total of wood over 2¾ inches diameter (derbholz) [a]	1,336,759,533	78.3	38.1
Stump and fagot wood	369,672,367	21.7	10.6
Total production	1,706,431,900	100.0	48.7

---

[a] Derbholz is a general term for all wood over 2¾ inches in diameter at the small end; therefore this term will cover saw logs, mine timber, posts, poles, and also such firewood as exceeds this dimension. Nutzholz applies only to saw-log timber, in distinction from all other kinds of derbholz.

Yield of all German forests, by States, for the year 1899–1900.

States.	Timber.	Per cent of derbholz.	Firewood.	Per cent of derbholz.

C

Yield of the German forests according to ownership, 1900.

	Yield per acre.	Derbholz—		Stump and fagot wood per acre.	Yield per acre.	Timber.	Total yield—	
		Timber.	Firewood.				Split and round firewood.	Stump and fagot wood.
	Cubic feet.	*Per cent.*	*Per cent.*	*Cubic feet.*	*Cubic feet.*	*Per cent.*	*Per cent.*	*Per cent.*
Crown forests	46.9	52.0	48.0	16.7	64.5	38.4	35.4	26.2
State and state managed	48.6	57.1	42.9	9.9	58.5	47.4	35.7	16.9
Communal	37.7	43.8	56.2	15.4	53.1	31.1	40.0	28.9
Institution	47.0	51.2	48.8	13.2	60.3	39.9	38.1	22.0
Association	29.1	35.8	64.2	15.4	44.5	23.4	42.0	34.6
Private	31.1	53.1	46.9	8.8	39.8	41.3	36.6	22.1
Entailed or in trust	42.9	55.9	44.1	10.7	53.4	44.7	35.3	20.0
Other private forests	27.7	51.8	48.2	8.3	36.0	39.9	37.1	23.0

The state forests evidently yield the largest per cent of timber.

Contribution of each class of ownership to total wood production of the German Empire.

	Timber.		Firewood.		Total derbholz.		Stump and fagot cited.		Per cent of the total wood area.
	Cubic feet.	Per cent.	Cubic feet.	Per cent.	Cubic feet.	Per cent.	Cubic feet.	Per cent.	
Crown, state, and part state forests	324,689,000	45.9	246,959,000	39.2	571,648,000	42.8	121,079,000	32.8	33.7
Communal and institution	105,794,000	15.0	131,669,000	20.9	237,463,000	17.7	93,616,000	25.3	17.6
Association	7,978,000	1.1	14,332,000	2.3	22,310,000	1.7	11,755,000	3.2	2.2
Private	268,139,000	38.0	237,181,000	37.6	505,320,000	37.8	143,212,000	38.7	46.5
German Empire	706,600,000	100.0	630,141,000	100.0	1,336,741,000	100.0	369,662,000	100.0	100.0

This shows that the state forests, with only 33.7 per cent of the total forest area, produce 43 per cent of the derbholz and 46 per cent of the timber; while the private forests, with 46.5 per cent of the total area, produce only 38 per cent of derbholz and of timber.

Timber yield of the German state forests in percentage of the total wood yield and of the yield of material over 2¾ inches in diameter.

Yield according to species.—The average yield of derbholz (wood over 2¾ inches in diameter) is greater for conifers than for the broadleaf species. The yield of the State forests in Wurttemberg per acre gives the following result:

Yield of State forests per acre.

Year.	Broadleaf species.			Conifers.		
	Total yield.	Wood over 2¾ inches diameter.	Fagot wood.	Total yield.	Wood over 2¾ inches diameter.	Fagot wood.
	Cubic feet.	*Cubic feet.*	*Per cent.*	*Cubic feet.*	*Cubic feet.*	*Per cent.*
1861-70	....	40.9	....	....	72.0	....
1874-76	59.3	40.9	31	91.8	81.9	11
1882	60.2	40.2	33	84.6	74.0	13
1888	72.6	53.4	27	91.8	79.6	13
1895	71.9	53.1	26	85.7	74.0	15
1900	77.0	59.4	23	91.4	78.5	14
1901	78.9	60.2	24	97.4	82.9	15

Forests in coppice and compound coppice yield less than high forests; e. g., in the state forests of Baden the yield per acre for high forests from 1892 to 1896 was 79.5 cubic feet, and from 1879 to 1901, 91.2 cubic feet; for coppice and compound coppice, from 1892 to 1896, 55.1 cubic feet, and from 1897 to 1901, 65.7 cubic feet.

The German Empire, with an annual production of 48.7 cubic feet per acre, shows the highest wood production of all European countries. Of the different kinds of forests, the state and crown forests produce the greatest amount of wood per acre per year—64½ cubic feet against 39.8 cubic feet in private forests. At the same time the state forests produce the largest percentage of saw-log timber—57.1 per cent against 53.1 per cent in private forests. Of all the States Saxony produces the largest proportion of saw-log timber. The different States may be arranged in the order of their production of saw-log timber as follows:

Distribution of saw-log timber by States.

States.	Per cent.	States.	Per cent.
Saxony	75	Brunswick	49
Saxe-Meiningen	57	Baden	48
Wurttemberg	55	Alsace-Lorraine	46
Prussia	54	Hesse	36
Bavaria	53	Mecklenburg-Schwerin	33

Although Prussia includes 59.1 per cent of the forest area of the Empire, it furnishes only 47.6 per cent of the total production of timber over 2¾ inches, and only 48.3 per cent of the timber production of the Empire; in each case less than half.

Bavaria, Wurttemberg, Baden, Alsace-Lorraine, Hesse, and Saxony, which together include 33.5 per cent of the total forest area, produce 44 per cent both of wood over 2¾ inches and of timber.

The largest percentage of saw-log timber does not necessarily mean production of the largest amount of all kinds of wood over 2¾ inches in diameter at the small end.

In the following table States with over 250,000 acres of woodland are arranged according to the production of derbholz:

Distribution of derbholz by States.

States.	Cubic feet per acre.	States	Cubic feet per acre.
Baden	58.4	Hesse	48.0
Wurttemberg	54.4	Bavaria	46.9
Brunswick	54.2	Pfalz	44.2
Alsace-Lorraine	51.5	On the right of the Rhine	47.0
Saxony	51.0	Saxe-Meiningen	46.2
Mecklenburg-Schwerin	48.1	Prussia	30.8

ANNUAL GROWTH AND PRESENT STAND.

Since the principle underlying the management of practically all the forests is to cut merely the annual increment and to leave intact the forest capital, it may be safely assumed that the annual cut is equal to the annual growth. In some cases the annual cut has been made smaller than the annual increment, in order to increase the forest capital so as to produce larger annual increments in the future.

The total present stand is given in the "Worterbuch der Volkswirtschaft" (Prof. D. L. Elster, Jena, Achte Lieferung, 1899), at a forest rotation of eighty to one hundred years, as from 70,000,000,000 to 105,000,000,000 cubic feet. Professor Elster assumes an annual growth of 50 cubic feet per acre, which corresponds very closely with the figure given above, 48.7 per cent. The average rotation may be taken as ninety years, but even this is too long, since there are many broadleaf forests which do not demand such long rotations. At an annual growth of 50 cubic feet and a rotation of ninety years, the forests will have a stand of about 79,000,000,000 cubic feet. At an average price even as low as 7 cents per cubic foot the German forests represent a capital of $5,530,000,000,[a] not counting the value of the land.

ANNUAL CONSUMPTION.

In spite of the fact that the German Empire succeeds in producing the largest amount of wood per acre, it is unable to supply its own needs for saw timber. Since 1863 the imports have exceeded the exports and the difference between them has been growing steadily. In 1904 this excess in saw-log timber (logs, sawn timber, and hewn timber) amounted to 4,726,000 tons, or 357,690,300 cubic feet (one ton being equal to about 75 cubic feet of round timber). This, together with the 1,706,431,900 cubic feet cut in Germany itself, gives a total home consumption of 2,064,122,300 cubic feet of wood of all kinds, or 36.6 cubic feet per capita. The consumption of saw-log timber alone is 1,064,322,000 cubic feet, or 18.8 cubic feet per inhabitant. The consumption of fuel alone is 999,800 cubic feet, or 17.8 cubic feet per capita.

---

[a] Stand=annual increment×area×rotation.

WOOD PRICES.

The two following tables give the wood prices in the state forests in the different States. The second table gives the average prices of wood, irrespective of the kind and species, for a period covering seventy-four years—1830–1903. The average prices for wood of all kinds do not vary a great deal. For 1902 the prices ranged from 5 cents per cubic foot in Prussia to 10 cents in Saxony, the prevailing price being about 7 cents. The first table gives the average sale prices as they prevailed in 1902 in the state forests for saw-log timber and firewood of different species. The highest saw-log prices were secured for oak timber, and the highest firewood prices were secured for oak and beech wood.

The figures for value per cord are about 4 per cent too high because the reducing factor .9 was used instead of 0.864. The figures for values per cubic foot are 4 per cent too high because the factor 0.007 was used instead of 0.006+.

Average prices per cubic foot of wood, irrespective of kind or species, in the state forests of the different States of the German Empire.

These are average prices obtained in the state forests, including the cost of cutting and working up the timber and delivering it along the road. They refer in Prussia and Bavaria to all kinds of wood, including stump wood, in Baden to all wood except stump wood, and in Saxony only to wood having a diameter of 2¾ inches at the small end.

FRANCE.

FOREST AREA.

The forests of France have increased to some extent since 1840, as may be seen from the following table:

Increase in forest areas, 1840–1903.

	Forest area.	Land area under forest.
	Acres.	*Per cent.*
1840	20,848,274	15.9
1862	23,026,445	17.2
1882	23,367,558	17.9
1903	24,021,587	18.2

The forest area of France is considerably smaller than that of Germany or Austria-Hungary. In 1901 the per capita forest area was 0.63 acre. The total area was distributed among different owners as follows: State forests, 2,889,470 acres, or 12.0 per cent; communal forests, 5,589,392 acres, or 23.3 per cent; and private forests, 15,542,725 acres, or 64.7 per cent.

Of state forests, a large part is poorly or not at all forested; the unproductive area is estimated as 662,000 acres, or nearly 23 per cent of the total area, while in the communal forests it amounts to 275,000 acres. Most of the state forests are in the departments of Ariege (203,750 acres), in the Pyrenees, Basses-Alpes (116,328 acres), Vosges (141,180 acres), Cote-d'Or (100,743 acres), farther Loiret (96,582 acres), and Corsica (111,890 acres).

The most of the communal and institution forests are in the eastern departments of Vosges (296,638 acres), Haute Saone (287,757 acres), Cote-d'Or (251,815 acres), Savoie (188,098 acres), Doubs (249,600 acres), Hautes-Alpes (197,948 acres), Jura (215,333 acres), Meuse (242,115 acres), in the more distant parts of the three departments of the Pyrenees (322,360 acres), and in Corsica (203,405 acres).

The smallest amount of private forest is found in the department of Vosges.

COMPOSITION.

Of the total area, 20 per cent is stocked with conifers and 80 per cent with hard woods (35 per cent of this is the ordinary oak and 4 per cent of the stone oak *Quercus ilex*.) In the state forests conifers occupy 23.4 per cent of the total area (fir 7 per cent, Scotch pine 6.6 per cent, maritime pine 4 per cent, spruce 2.7 per cent, larch 1.8 per cent, other conifers 1.3 per cent); broadleaf forests 76.6 per cent (oak 27.4 per cent, beech 18.3 per cent, hornbeam 10.9 per cent, evergreen oak (*Q. ilex*) 4 per cent, other hard woods 16 per cent). In private forests conifers form 19 per cent, hard woods 81 per cent.

According to the system of management practiced, the forests show the following proportions in state, private, and communal forests:

Distribution of forests by management.

	State forest.	Forests under state control.	Private forest.	Total forest area.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*
Coppice	2.5	14.7	49.0	38.0
Composite forest	29.2	53.2	31.0	35.0
Conversion forest	16.8	1.0	....	2.0
High forest	51.5	31.1	20.0	25.0

ANNUAL CUT.

The total annual cut in France amounts to 910,740,000 cubic feet, of which 225,920,000 cubic feet are timber, or a total cut of 39.39 cubic feet per acre. The cut varies in the different forests, as can be seen from the following figures:

Annual cut per acre by ownership.

	Total cut per acre of forest area.	Timber.
	Cubic feet.	*Per cent.*
State forest	43.07	35
Forests under state control	36.57	24
Private forests	40.95	25
Average	39.39	25

ANNUAL GROWTH.

While France has still much work to do before she can bring the exploitation of her forests to the point the German forests have reached, it can hardly be doubted that the present cut does not exceed the annual growth. The present yield of 910,740,000 cubic feet per year may, therefore, be considered equivalent to the total annual growth. The chief task which France has in the future is to produce a larger amount of saw-log timber in proportion to cord wood, which has a small value. The 910,740,000 cubic feet of home product are not sufficient to supply all her needs, and it is necessary to import wood for home consumption. Not counting firewood and charcoal, France has at present on an average every year a surplus of imports over exports of 44,000,000 cubic feet in round numbers. On an average, between 1894 and 1898, the following amounts of the different kinds of wood were exported and imported:

Exports and imports of wood, in cubic feet.

In form of—	Exports.	Imports.	Surplus of imports over exports.
Sawn lumber	3,277,000	74,509,000	
Logs and other round timber	43,747,000	6,721,000	
Staves	212,000	6,011,000	
Other wood, except firewood and charcoal	3,101,000	8,650,000	
Total of all kinds of wood	50,337,000	95,891,000	45,554,000

As regards firewood and charcoal, there were exported 5,129,000 cubic feet and imported 3,443,000 cubic feet; in other words, the exports exceeded the imports by 1,700,000 cubic feet, which reduces the surplus of imports over exports of all kinds of wood to 43,900,000 cubic feet.

The total home consumption, therefore, amounts to 910,740,000 plus 43,900,000 cubic feet, or a total of 954,640,000 cubic feet. The per capita consumption is 24.6 cubic feet, of which 17.7 cubic feet are firewood and 6.9 cubic feet are timber.

WOOD PRICES.

The following table gives prices for saw-log timber of different species at point of shipment along the road:

Wood prices per cubic foot, according to size of log, at points of shipping for Paris market at city gates.

SAW LOGS.

Species.	Price.
Oak, heartwood	$0.28 to $0.42
Oak, sapwood	.42 to 1.10
Beech	.25 to .34
Ash	.17 to .34
Red elm	.20 to .34
White elm	.22 to .29
Scotch pine	.13 to .18
Spruce and fir	.18 to .30

RAILWAY TIES (1905).

Contents in cubic feet.	Price per tie.
4.0	$1.08
5.4	1.45
5.7	1.54
7.2	1.94
7.6	2.04

BELGIUM.

FOREST AREA.

The present forest area of Belgium shows an increase over that of 1846, as may be seen from the following:

1846, 1,200,268.8 acres; 1866, 1,074,057.3 acres; 1880, 1,209,556.8 acres; and 1895, 1,303,735.5 acres.

The forest area forms 17.7 per cent of the total land area, or 0.2 acre per inhabitant. The most wooded provinces are Luxemburg, 41 per cent, and Namur, 31 per cent, which together comprise 666,937 acres. Of the total forest area, 62,600 acres, or 4.8 per cent, are state forests; 395,452 acres, or 30.3 per cent, are communal forests; 17,370 acres, or 1.3 per cent, belong to public institutions; and 828,300 acres, or 63.5 per cent, are private forests.

COMPOSITION.

Of the total forest area, 71.1 per cent are hard woods and 28.9 per cent are conifers (pine predominating). Of the hard woods, 56 per cent was managed as composite forest, 31 per cent as sprout forest, and 13 per cent as high forest. Especially common is oak coppice wood, managed for bark, the production of which amounts to about 29,500 tons.

ANNUAL CUT.

The annual cut is estimated as 75,789,000 cubic feet, or 58.2 cubic feet per acre, of which saw-log timber forms 40 per cent, or 28,734,200 cubic feet. In addition, some 7,415,100 cubic feet are obtained annually from trees outside of the forest, making the total cut 83,204,000 cubic feet.

ANNUAL GROWTH.

During recent years Belgium has manifested a strong tendency not only to husband her forests most rationally, but also to increase the forest area. The annual cut may, therefore, be taken as the annual growth. There are no recent figures regarding the productivity.

CONSUMPTION.

Home production is unable to satisfy the needs of the country. The consumption of mine timber alone in 1894 was 21,892,210 cubic feet and in 1903 it was 35,310,000 cubic feet. The excess of imports over exports of building timber in 1898 amounted to 36,400,126 cubic feet. The total consumption then amounts to 119,604,126 cubic feet, or 17.7 cubic feet per capita. Of this amount, 72,549,400 cubic feet, or 10.8 cubic feet per capita, consist of saw-log timber; while 47,055,000 cubic feet, or 6.9 cubic feet per capita, are cord wood.

WOOD PRICES.

The wood prices are very much the same as in Germany. The average price for all kinds, irrespective of species, is something like 6 cents per cubic foot in the forest. In Germany, as we have seen, the price of wood in the forest ranges between 5 and 8 cents, while cord wood in Prussia sells at about 3 cents.

SPAIN AND PORTUGAL.

The figures regarding the forests of Spain and Portugal are extremely conflicting; thus, according to K. van Scherzer,[a] the area of Spanish forests in 1885 was 26,098,200 acres, or 20.8 per cent of the total land area; and for Portugal, according to the same source, 1,756,000 acres, or 8 per cent of the total land area. According to A. Mélard,[b] the forest area in Spain may be taken as equal to 16,065,000 acres, and that of Portugal from 1,112,400 to 1,236,600 acres. Taking Melard's figures, it would seem that the forests of Spain occupy 13 per cent of the total land area and those of Portugal 5 per cent. According to Scott Keltie,[c] the forests of Portugal amounted to only 2.9 per cent of the total land area.

The Spanish peninsula is a plateau bordered by high mountain terraces. The rivers are unreliable, having neither glaciers nor great lakes at their sources. The rains are very unequally distributed over the different seasons. Drought is often followed by severe floods, and in order to counteract their bad effects Spain and Portugal should be well forested. Both countries, however, are lacking in this respect. As to the forest area per inhabitant, taking Mélard's figures for the areas, Spain, with a population of 18,090,000, has a forest area per capita of 0.88 acre, and Portugal, with a population of

---

[a] Das Wirthschaftliche Leben der Völker.

[b] Insufficance de la Production de bois d'œuvre.

[c] The Statesman's Yearbook for 1901.

5,423,000, has only 0.23 acre. These figures can not, however, be considered reliable, and if Spain actually has nearly 0.9 acre for every inhabitant the forest must be uncommonly poor, because Spain has not enough timber to satisfy rather low home demands for wood. The forests probably meet a great deal of the local demand and furnish large amounts of cork for export, but on the whole they are not sufficient to supply the home consumption. The need for foreign timber will still further increase when Spain enters on an active exploitation of her mineral wealth.

There are no figures of any kind in regard to the annual cut, growth, or consumption for either country.

ITALY.

FOREST AREA.

According to Loreto Pasqualucci,[a] the forest area of Italy now comprises 11,034,900 acres, but this figure is higher than that given in the official Italian reports.[b] The official statistics[b] of this country give the area of forests as 10,115,404.2 acres, or 14.28 per cent of the total land area. The forest area per capita is 0.31 acre.

The government ownership of forests is of two kinds. One part of the state forests, 375,000 acres in extent, is under the direct control of the secretary of the treasury, and any portion of it may be sold whenever necessary; another part, much smaller in area, comprising only 40,000 acres, is declared inalienable, is directly under the secretary of agriculture, and is administered by the forest service. The largest state forest (28,245 acres) is in Tuscany, and two other large forests (one of 16,137 acres, the other of 14,840 acres) are in Venetia.

COMPOSITION.

Of the total forest area 52 per cent is managed as high forests and 48 per cent as composite and sprout forests. Of the high forest 30 per cent is coniferous, 62 per cent produces hard woods, and 8 per cent is mixed forest. The forests are thus shown to be principally hard woods.

ANNUAL CUT.

According to official statistics the following amounts were cut in all the forests: Saw-log timber, 48,525,000 cubic feet, or 4.8 cubic feet per acre; cord wood, 222,103,000 cubic feet, or 22 cubic feet per acre, and wood for charcoal, 106,621,000 cubic feet, or 10.5 cubic feet per acre, making a total of 377,249,000 cubic feet, or 37.3 cubic feet per acre.

In addition, by-products were obtained amounting to 1,708 tons. Thus enormous quantities of cord wood and wood for charcoal were obtained.

ANNUAL GROWTH.

There are no figures regarding the productivity of the forests. It can not, however, be very far from the annual cut.

[b] Annuario Statisco Italiano 1898 ed., 1900.

CONSUMPTION.

The 377,252,000 cubic feet which are cut at home are not sufficient to supply the needs of the home industries. Italy is compelled to import, though not to the same extent as England, Germany, France, and Belgium, because its industries are less developed. The average excess of imports of saw-log timber over exports, for a period of five years (1895 to 1899), was 27,023,000 cubic feet, and the yearly excess of imports of cord wood over exports for the same period was about 3,031,000 cubic feet. The total consumption of saw-log timber may therefore be taken as 75,548,000 cubic feet, or 2.4 cubic feet per capita. The total consumption of cord wood and wood for charcoal was 330,000,000 cubic feet, or 10.5 cubic feet per inhabitant. The aggregate consumption per capita is thus nearly 13 cubic feet.

WOOD PRICES.

No figures are available regarding the prices of wood.

NETHERLANDS.

FOREST AREA.

In the Netherlands for the last sixty-five years there has been a constant increase in the area of productive land at the expense of the noncultivated and waste land; thus, in 1833, fields, pastures, meadows, and forests occupied 63 per cent of the total land area, and the remaining 37 per cent was swamps, waste land, and roads, while in 1898, 72 per cent was under crops, forests, and gardens. In sixty-five years the Dutch have thus transformed 9 per cent of waste and unproductive land into profitable areas. Forests have also increased accordingly; in 1833 the forest area was 417,728 acres, or 5.2 per cent of the land area; in 1881 it was 552,001 acres, or 6.8 per cent of the land area; and in 1889 it was 617,567 acres, or 7.7 per cent of the land area.

The forest area in sixty-five years has increased about 50 per cent. Since the greater part is in the hands of private individuals, this increase must be taken as an indication that forestry is profitable. The per capita forest area is 0.1 acre.

COMPOSITION.

By species, the forests are distributed as follows: Two hundred and twelve thousand five hundred acres, or 37.8 per cent, are coniferous forests (pine), and 350,572 acres, or 62.2 per cent, are hard woods (chiefly oak). The sprout forest is the prevailing form of management. The oak sprout forest comprises 91,892 acres, or 16 per cent of the total forest area.

ANNUAL CUT AND GROWTH.

Unfortunately there are no reliable figures concerning the amount of annual cut. K. von Scherzer[a] estimated the cut in Holland and Belgium at 37 cubic feet per acre. Judging by the revenues obtained in the Belgian forests, the Dutch forests must yield a larger amount of wood per acre, at least 46 cubic feet. In that case the total cut would amount to 28,591,000 cubic feet. This figure may also be accepted as the annual growth, as the forests are managed for a sustained yield.

---

[a] Das wirthschaftliche Leben der Völker.

CONSUMPTION.

The annual yield is not sufficient to supply the home consumption. Holland is a highly commercial nation, but its industries are less developed than those of Belgium, and hence its wood consumption is smaller. Holland uses enormous quantities of coal and turf, and therefore does not use much wood for fuel, but it needs large quantities of timber for building purposes. The surplus average of imports of round timber over exports for five years (1895–99) was about 24,875,000 cubic feet, and that of sawed timber for the same period, 13,757,000 cubic feet, or in all 38,632,000 cubic feet. Adding to this the annual cut at home (28,591,000 cubic feet), the total consumption in Holland would be about 67,200,000 cubic feet, or, with a population of 5,100,000, 13.1 cubic feet per capita. Even assuming that 50 per cent of the total cut is cord wood, still the consumption of cord wood would form only 2.8 cubic feet, while the consumption of timber and lumber would be 10.3 cubic feet per capita.

WOOD PRICES.

Except the general import prices per cubic foot as they are obtainable by dividing the total value of imports by their volume, no other wood prices are available. The general import price for round timber was about 14 cents per cubic foot, and that of sawed timber about 18 cents.

SWITZERLAND.

FOREST AREA.

The Swiss forests occupy 20.6 of the total land area of 10,237,560 acres, or 2,140,012 acres, while in 1884 the forest area amounted to only 1,940,465 acres. In other words, the forest area has increased 10 per cent during the last fifteen years. The Government recognizes the necessity of keeping the mountain slopes covered with forests in order to avoid landslides, and therefore extends the area under forest by all possible means, chiefly by planting. Between 1878 and 1890, 10,000,000 conifers and 1,000,000 broadleaf trees were planted on an average every year. Since 1890 the planting has been done every year regularly. In 1899 about 14,000,000 pine seedlings, 2,000,000 spruce, 1,200,000 larch, and 1,400,000 fir and other trees were planted. The area planted during this whole time amounted to 4,153 acres, at a cost of $22.25 per acre. The forest area per capita is 0.65 acre.

Of the total forest area, the States own 97,630 acres, or 4.6 per cent; communes and corporations, 1,431,280 acres, or 66.9 per cent; and private individuals, 611,102 acres, or 28.5 per cent. The most heavily wooded cantons are Schaffhausen, Lolothurn, Basel-Land, and Aargau; the least thickly wooded are Genève and Uri. The distribution of forests according to ownership in the different cantons is given as follows:

Distribution of forest in different cantons.

Cantons.	Forest area.	Land area under forest.	State forests.	Communal and corporation forests.	Private forests.
	Acres.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*

ANNUAL CUT.

Unfortunately, the latest statistics do not contain any figures for the forest cut, but the earlier statistics do contain such, and since there could not be any great change in the amount of cutting, these figures may serve our purpose.

In the early eighties the cutting, according to Professor Landolt,[a] in state forests amounted to 5,509,400 cubic feet, or 68 cubic feet per acre; in communal and corporation forests, 65,653,560 cubic feet, or 51 cubic feet per acre; and in private forests, 27,335,400 cubic feet, or 48 cubic feet per acre, making a total of 98,498,000 cubic feet, or an average of 51 cubic feet per acre.

Of the total cut, 40 per cent formed saw-log timber for building purposes.

ANNUAL GROWTH.

The cut of 51 cubic feet per acre, or a total of 98,498,000 cubic feet, may be taken as representing the annual growth of all the Swiss forests, since Switzerland has for a long time been practicing forestry and became converted to the principle of cutting only the annual increment, leaving the forest capital which produces that increment.

CONSUMPTION.

The comparatively large annual cut ought to be sufficient, apparently, for a population of about 3,000,000 inhabitants (in 1900 there were 3,117,000); but as a matter of fact Switzerland is compelled to import timber from abroad, and the figures for imports and exports for the fifteen years following 1885 show that the imports are constantly growing while the exports are constantly decreasing. Timber is obtained chiefly from Germany, Austria, and France. By aid of the figures for exports and imports and the amount cut in the forests, the wood consumption, in cubic feet, for the period from 1895 to 1899 may be determined as follows:

---

[a] A. Furrer. Volkswirtschafts der Schweiz.

	Saw-log timber.	Firewood.
Annual cut	40,000,000	60,000,000
Excess of imports over exports	8,500,000	8,500,000
Total	48,500,000	68,500,000

The total consumption is 117,000,000 cubic feet, or 38 cubic feet per inhabitant. Of this, 15.7 cubic feet are in the form of saw-log timber and timber for building purposes and 22.3 cubic feet in the form of firewood.

WOOD PRICES.

The stumpage prices of saw-log timber and construction timber at the place of cutting, 1895–1899, was 8.4 cents per cubic foot, and for firewood nearly 5 cents. The average price for both timber and firewood was 6.3 cents per cubic foot. These prices are practically the same as those in Prussia.

DENMARK.

FOREST AREA.

The forest area of Denmark in 1899 comprised 623,575 acres, or 6.3 per cent of the total land area, and a per capita of 0.25 acre. The islands Seeland, Bornholm, Laaland, Falstr, and Fyen, occupying 9.3 per cent of the total area of Denmark, contain 300,137.5 acres of forest land, or 49.7 per cent of the total forest area. The other half of the Danish forests, 328,437.5 acres, or 50.3 per cent, are found on the mainland (Jutland).

The state forests comprise 23.8 per cent, or 143,702.5 acres; of this area, 45.8 per cent is found on the Danish islands and 54.2 per cent on Jutland.

COMPOSITION.

Of the total forest area 266,515 acres, or 44.2 per cent, are beech forests; 90,622 acres, or 15 per cent, are other hard woods; 228,625 acres, or 37.9 per cent, are coniferous forest; and 17,812 acres, or 2.9 per cent, are scrub growth.

Of the total area of state forests, 42,197 acres, or 29.3 per cent, are hard-wood forests (chiefly beech); 49,917 acres, or 34.8 per cent, are coniferous forests; 41,822 acres are on barren land; and 9,767 acres, or 6.8 per cent, are not on true forest soil. The area of productive state forests is therefore only 92,114 acres. The large proportion of unproductive land in the state forests is due to the vast areas of heathland found on Jutland and the island of Bornholm. It is interesting that the coniferous forests of Denmark are all planted, the first conifers having been introduced at the end of the eighteenth century. On the island Bornholm is found even the silver fir.

ANNUAL CUT, GROWTH, AND CONSUMPTION.

Unfortunately, there are no figures regarding the cut and growth or any data concerning wood consumption. Denmark fully appreciates the value of forests and treats most carefully those few which she possesses, and tries to increase the area as far as possible by planting the waste lands. Unfortunately, the area of forests is very small and the production far too little for a population of 2,300,000 inhabitants. The total productive forest area is probably not over 575,000 acres. Assuming that the forests of Denmark are producing annually as much as the forests of Holland—that is, 45 cubic feet per acre—the annual production of wood in Denmark would be 25,875,000 cubic feet. In addition to this, Denmark imports about 22,951,500 cubic feet of structural timber, or a total of 48,826,500 cubic feet. With a population of 2,465,000 the wood consumption is 19.8 cubic feet per capita.

BULGARIA.

FOREST AREA.

The agricultural statistics for 1897 credit Bulgaria with 7,169,675 acres of forests, while the forest statistics give 7,602,815 acres, or 30 per cent of the total land area. Of this, 4,375,490 acres lie within 1,200 feet of sea level, 1,614,000 acres lie between 1,200 and 3,000 feet in elevation, and 1,613,325 acres at an altitude above 3,000 feet. Only 375,000 acres of the state forests are accurately measured.

The Balkan Mountains are the most heavily wooded, especially the eastern half. Northern Bulgaria, especially the Danube region, is most sparsely wooded. In Dobrucha, along the Black Sea, dried manure is used for fuel. The forest area per capita amounts to 2.4 acres, varying from 0.2 to 10.4 acres per capita in the different provinces. The State owns 29.6 per cent, communes 51.4 per cent, and private individuals 19 per cent of the total forest area. Until 1869 the cutting of timber and grazing in the state forests were entirely free; since that year they have been brought under regulation, though not without a great deal of friction between the Government and communities.

COMPOSITION.

Hard woods (oak, beech, and, in the south, walnut) predominate. Conifers occur only in the mountains.

Bulgaria may be truly called a rural country, since five-sevenths of the total population live in villages and are engaged in agriculture. There is no rational forest management, and practically nothing is known of the condition of the forests.

SERVIA.

Data regarding Servian forests are extremely conflicting. Thus Mélard[a] gives the extent of the forests of Servia at 5,225,000 acres, or

---

[a] Insuffisance des bois d'ouvre.

42 per cent of the total land area. Kolm[a] gives the forest area as 4,500,000 acres; Keltie[b], as 1,202,500 acres; and Endres as 3,864,774 acres, or 32 per cent of the land area. Since the figures given by Endres[c] are more recent, his estimate is undoubtedly the most reliable. The forest area per capita may be taken then as 1.55 acres. According to ownership the forests are divided as follows: State forests, 1,417,230 acres, or 36.6 per cent of the land area; communal forests, 1,645,650 acres, or 42.6 per cent; church and monastery forests, 42,707 acres, or 1.1 per cent; and private forests, 759,187 acres, or 19.7 per cent, making a total of 3,864,774 acres, according to Endres.

The boundaries of the different forest owners are, however, very uncertain and still disputed. The eastern part of Servia is very little wooded. Hard woods (beech and oak) occur chiefly in the east and north, while conifers (fir, spruce, pines) are found in the west and south. On the whole, the broadleaf forests predominate. Every citizen has the right to cut timber for his own needs in the state forests; it must, however, be paid for if cut for sale. Under such a system of cutting there can hardly be any regular forest management. From the fact that in 1903 Servia had an excess of imports over exports amounting to 5,846,000 cubic feet it must be inferred either that the forests are not yet opened up or that they are already ruined by abuse, because with a forest area of 1.55 acres per capita and undeveloped industries, the forests should be fully able to supply the needs of home consumption.

No figures are available regarding the cut, yield, or consumption of wood.

GREECE.

FOREST AREA.

The forests of Greece occupy 2,023,380 acres, which is less than 13 per cent of the total land area. The forest area per inhabitant is 0.83 acre. Greece was once thickly wooded, and in ancient times had a large merchant marine and navy for that period. All the ships built were supplied with wood from the neighboring mountains. Because of her large merchant marine, supplied from her forests, and the great number of warships built from the timber grown in her own forests, Greece was able to extend her commerce throughout the Mediterranean and to maintain her independence.

Now the forests are gone or are being devastated rapidly. Reckless cutting, fires, and grazing will soon complete the destruction in a country where forests are greatly needed. Nine-tenths of Greece is mountainous. The rivers have a rapid fall and resemble torrents, drying out in summer, and causing floods and destruction in autumn and winter.

Information regarding forests and forestry is extremely meager. From the fact that agriculture is at a very low level, one may safely infer that forestry is in no better condition. The chief cause of such unwise use of the natural resources must be sought in the ignorance of the people. According to Keltie, 30 per cent of all recruits admitted to military service are entirely illiterate, and only 15 per cent can read.

---

[a] Serbien; W. Kolm (Semlin, 1894).

[b] The Statesman's Yearbook; Scott Keltie (London, 1901).

[c] Handbuch der Forstpolitik; Endres (Berlin, 1905).

Although industrially undeveloped, Greece has not enough wood to provide for home consumption. Annual imports amount to 275,387 cubic feet.

TURKEY.

It is impossible to obtain figures for a country which, like Turkey, does not officially recognize the value of statistics. The forest situation in Turkey is no better than in Greece. There may still be some remote corners of merchantable forest, but the country as a whole must be very poor in this respect. Here, as in Greece, the ravages of man and beast are equally severe, and in the few forests remaining the destruction exceeds production.

* * * * * * *

The countries so far considered are those whose natural resources have been more or less fully explored and whose forests yield large quantities of materials in common use, which can be delivered at a low price to market.

The forests of the rest of the world may be and are botanically rich in species, but do not have great commercial value because they lack the kinds of wood needed in commerce and industry by the 250,000,000 people composing the most advanced and powerful nations of Europe. The richest forests in Europe, commercially, are those of Sweden, and yet botanically they are very poor, containing but two principal species, Scotch pine and spruce. The forests of the regions which were not considered in the previous pages will now be discussed under continents; and since our knowledge concerning those forests is, in the majority of cases, very meager, they can be treated only in a general way.

ASIA.

The forests of British East India, Japan, Siberia, and Caucasus were mentioned before. The forests of the Philippines will be taken up in connection with those of the United States.

CHINA.

The forests of China are practically unknown. Undoubtedly there must be some forests, since wood is used for building homes, etc. In Manchuria, in the three eastern provinces of the Chinese Empire, there are apparently large forests, but nothing is known of their extent. The species of economic importance in Manchuria are birch, alder, oak, maple, elm, cork tree, poplar, ash, fir, spruce, pine, and willow. The forests must be sufficient for local needs. As to the western provinces of China, they need foreign timber and receive it from the United States and Canada.

The imports are not very great as yet, but have increased considerably compared with the imports of the sixties and seventies. From the United States and Canada, China receives principally saw timber. Eventually, when the country enters upon active construction of railroads, the demand for timber will increase enormously. With 380,000,000 people, when it becomes an industrially developed country, China will be a large buyer of wood in the world's market.

PERSIA.

This country is almost treeless. Over the largest part of it trees grow only in parks surrounding cities. Only the Caspian provinces are rich in forests of all kinds. Here, on account of the fertility of the soil, abundance of moisture in the soil, and high temperature, vegetation is extremely luxuriant and dense. The whole northern slope of the Elburz Mountains, skirting the southern shore of the Caspian, is covered with forests. In this region many species are found—elm, oak, plane tree, cherry, plum, etc.; but the most valuable tree is the palm (*Buxus sempervirens*), from which is extracted a gum which is used by the people for chewing. It is considered very good for preserving the teeth and is a disinfectant. In Europe the *Buxus sempervirens* is used in engraving. This tree is now practically exterminated in all places where it was accessible, being now only found in the northwestern extremity of the Caspian region.

BRITISH POSSESSIONS IN ASIA.

CEYLON.

Next to East India, Ceylon is the most heavily wooded Asiatic possession of Great Britain. Its forest area is given as 6,762,880 acres, or 42 per cent of the total area of the island.

The number of species is very great, among which ebony and satinwood are the best known. In general the composition comes very close to that of British India; beside the species found in British India, the bamboo, eucalyptus, beech (*Fagus religiosa*), and a great number of others are found.

The local consumption of big timber is small. Although Ceylon exports rare woods, like ebony and satinwood, it needs timber for construction and has an excess of imports over exports.

The Ceylon climate is adapted to growing rubber trees, and this industry has been started on a large scale. At the close of 1900 there were 1,763 acres of all kinds of plantations.

THE FEDERATED MALAY STATES.

The total forest area of the Malay States is not known, except that the British Government has established several forest reserves with an aggregate area of 101,560 acres.

THE STRAITS SETTLEMENTS.

According to Mr. H. C. Heel, late inspector-general of the forests to the government of India, 88,320 acres, or 9 per cent of the total area of the Straits Settlements, have been declared reserved state forests. The colony exports a great deal of rubber, and the cultivation of rubber plants is a profitable enterprise.

CYPRUS.

The island of Cyprus, lying in the Mediterranean Sea in Asia Minor, is on the whole scantily wooded. An area of 448,000 acres is classed as forest, but many parts of this are of more or less open character. The most common tree is maritime pine. There are also found *Pinus laricio*, several species of oak, plane tree, alder, cedar, cypress, juniper, elm, and walnut. *Rhus coriaria* (the sumac of commerce), carob, and olive flourish.

TERRITORIES OF THE BRITISH NORTH BORNEO AND SARAWAK.

The total forest area of Borneo and Sarawak is not known. The territories are rich in timber and other products of the forest, as gutta-percha and india rubber. The exports of timber exceed the imports in volume.

FRENCH POSSESSIONS IN ASIA.

The forests of the Indo-Chinese possessions of France and countries under its protectorate are large, but are very little known and very little used, although they include almost the same species as are found in the forests of British India.

DUTCH POSSESSIONS IN ASIA.

Large forest areas are found in the colonies of the Netherlands, on the islands of Java and Sumatra, and part of Borneo. The forests of Java are most known. They comprise 4,920,000 acres.

AUSTRALIA AND OCEANIA.

In Australia forests in the European sense are very seldom met with, except in the form of a few thousand acres of artificial plantations. The Australian forest exists either as thicket, open forest, or chapparral growth. The tree-forest region of the mainland is almost entirely along the coast. The areas under forest in the different colonies have been estimated as follows:

Area of forests by colonies.

Colony.	Area of forests.	Land area under forest.
	Acres.	*Per cent.*
Queensland	39,680,000	9.0
New South Wales	19,840,000	10.0
Victoria	11,520,000	20.0
South Australia	3,840,000	.7
West Australia	20,480.000	3.3
Tasmania	10,880,000	65.0
New Zealand	20,480,000	31.0
Total or average	126,720,000	19.8

The distribution of forests in Australasia, as may be seen from this table, is very different in the various colonies. Thus while in South Australia the forest does not occupy 1 per cent of the total land area, in Tasmania it forms more than half the total area.

The mainland and Tasmania are the home of the eucalypts and wattles. New Zealand, especially in the northern island, is rich in conifers, of which the Kauri pine is the most valuable. The thicket forest of Australia, especially of the east coast, has a primeval character. The open forest contains chiefly hardwoods, especially the eucalypts, and the chaparral forests contain acacias.

Recently nearly all colonies have withdrawn smaller or larger areas as timber reserves, the exploitation and care of which is regulated by law. Thus in Queensland, of the 40,000,000 acres, 1,500,000 acres have been declared timber reserves; in New South Wales, of the 20,000,000 acres of timber lands, 6,000,000 acres have been withdrawn from settlement, but not in perpetuity; in South Australia, of the 3,840,000 acres, 217,000 acres were declared reserves under the forest law of 1882, but of this area only one-fifth contains timber of commercial value, the rest being stocked with stunted trees and scrub; in addition, there are 13,000 acres planted chiefly to sugar gum, pines, American ash, and other trees; in West Australia there are 20,480,000 acres of timber lands, and more than four times as much jungle covered with small trees and scrub.

In the following statement are shown the most important trees in West Australia, the areas which they cover, and the quantity of timber standing on them:

Area and stand of timber of principal species in West Australia.

Species.	Area of forests.	Total commercial timber.	Per acre
	Acres.	*Cubic feet.*	*Cubic feet*
Jarrah	8,000,000	2,000,000,000	250
Karri	1,200,000	750,000,000	625
Tuart	200,000	15,000,000	75
Other species	11,000,000	350,000,000	30
Total	20,400,000	3,115,000,000	150

No timber land has been placed in reserves. Tasmania, with 11,000,000 acres of forest, equal to 65 per cent of the total area of the island, has a reservation of 266,000 acres; it is, however, subject to revocation at any time by the governor.

The forest area of New Zealand is variously estimated at from 20,000,000 acres, or 31 per cent of the total area, to only 12,000,000 acres; by an act of 1885, 1,250,000 acres were declared timber reserves. In Victoria, of the 11,520,000 acres, 5,500,000 acres have been declared reserves under the act of 1890.

Thus the colonies of Australasia possess an area of nearly 15,000,000 acres, corresponding to the state forests of Europe. A great part of this area, however, may be reopened to settlement.

There are only fragmentary figures regarding the cut in the forests of the Australian colonies. Tue cutting is leased under a system of royalties or licensing fees. While West Australia, Tasmania, and Queensland have an excess of exports over imports, Victoria, New South Wales, and South Australia have an excess of imports over exports. For Australia, as a whole, the imports at present exceed the exports, and therefore it must be classed among the countries deficient in timber. The forest area of Australia ought to be sufficient to supply fully the local needs. New Zealand also, with its mild and moist climate and its great mountain chains and magnificent coniferous forests, resembling those of the northern hemisphere, ought to be able to supply large quantities of timber for export to her neighbors. Some statisticians, like Mélard, think that the forests of Australia have been devastated, and that a country which lives by sheep (in 1896 Australia possessed 89,745,000) can not raise at the same time both sheep and forests, as sheep require daily more extended grazing grounds at the expense of the forest. Others believe that the forests of Australia are not opened yet, and that eventually they will be fully able to supply enough good timber at least for home consumption. At present the deficit is covered by importations from the United States, Sweden, and Russia.

HAWAII.

The total area of native forests in Hawaii has recently been computed as 1,174,992 acres. In addition to this is the Algaroba forest of approximately 50,000 acres. There are established at present in Hawaii 16 forest preserves, comprising in all 444,116 acres.

The forests resources of Hawaii will be more fully discussed in connection with those of the United States.

AFRICA.

The forests of Africa are as yet very little explored. There is no doubt that in some parts of it there are to be found very valuable trees. The French and English colonies are best known.

FRENCH POSSESSIONS IN AFRICA.

ALGIERS.

In 1900 the forests of Algiers occupied an area of nearly 8,000,000 acres, a great portion of which is unproductive. The State owns 6,250,000 acres, or 77 per cent of the total; private individuals, 1,250,000 acres; and communes, 192,000 acres. Forests occupy in different parts of the country from 4 to 25 per cent of the total land area.

Botanically, the Algerian forests are very rich. The principal species are: Cork oak (1,025,000 acres), and pine (2,000,000 acres); other species cover 470,000 acres.

TUNIS AND OTHER COLONIES.

In Tunis the forests occupy 2,027,000 acres, nearly all in the northern part of the country. Like the Algerian forests, they are greatly devastated by fires and grazing. The productive area is probably not more than 1,630,000 acres. Of this the State owns 1,158,740 acres, or 77 per cent; the rest belongs to private individuals, societies, etc. The prevailing species is oak; cork oak occupies 290,000 acres; all other oaks, 117,500 acres.

The island of Madagascar has about 25,000,000 acres of forest, or 19 per cent of the total land area.

All other African possessions of France contain valuable species, but the extent of the forests is little known.

BRITISH POSSESSIONS IN AFRICA.

SOUTH AFRICA.

The total forest area of South Africa in May, 1905, was 640,902 acres.[a] This area includes the whole of South Africa south of the Zambesi, with the exception of Rhodesia and Portuguese East Africa, for which data are wanting. While there is forest of some economic importance in the Portuguese territory and on the Rhodesian plateau, none of the regions have any appreciable area of dense forest comparable to that of Natal, Cape Colony, and Transvaal. This forest area is distributed as follows among the different colonies: Cape Colony, 529,902 acres; Natal, excluding scrub forest, 90,000 acres (old Natal, 40,000, and Zululand, 50,000); Swaziland, 1,000 acres; and Transvaal, 20,000 acres; making a total of 640,500 acres.

Deducting from this total area the very poorly stocked cedar forests, there remains 524,408 acres of yellow wood (*Podocarpus elongata* and *P. thunbergii*), the most valuable species of South Africa. Of this amount, 23,535 acres are artificial plantations. As may be seen from these figures, Cape Colony contains the largest amount of forest, which represents not quite 0.3 per cent of the total area of the colony. The forest area per inhabitant in 1901 was 0.22 of an acre, which is not sufficient to supply the needs of the people.

Very little definite information exists in regard to the forest areas in the other British possessions in Africa, such as the west coast of Africa, the East Africa Protectorate, Uganda Protectorate, Central Africa Protectorate, the Soudan and Mauritius, beyond the amounts of exports of rubber and gums. One thing is certain, and that is that they do not contain sufficient timber to supply their own needs.

Mélard divides Africa, in accordance with the distribution of rainfall, into four zones, parallel to the equator: the Atlas and Mediterranean slopes; the Sahara; the equatorial zone; and the South Africa zone.

The Atlas and Mediterranean slopes comprise Tunis and Algeria and the other French colonies, the forest resources of which have been discussed above. The South African zone includes the British and Portugese possessions, the forest resources of which have also been discussed. There remains now to say a few words about the Sahara and the Equatorial zones.

The Sahara, with the exception of small oases where palms are cultivated, has no forests. Egypt belongs to the Sahara zone; it has no forests, and its demand for timber is constantly increasing as a result of the growing industries and the extension of railroads.

The Equatorial zone is supposed to contain virgin forests able to replace Canada and Sweden in the market. Mélard shows that the Equatorial forest is much less rich and extensive than has been thought. Near the Gulf of Guinea, between 10° N. and 4° S., there is a wooded area which is estimated at from 45 to 60 miles wide. East of this zone are found savannas, covered for hundreds of miles with coarse grass and scrub growth. Such is the Soudan, the

---

[a] Forests in South Africa, D. E. Hutchins, Capetown, South Africa; from Science in South Africa, August, 1905.

French, and the Belgian Kongo as far east as the upper basin of the Kongo River and its tributaries, where another large forest area is found. The Equatorial zone thus consists of two great forests, one along the western coast of Guinea and the other in the center on the upper basin of the Kongo River, divided by a vast treeless area. No definite information exists about these tropical forests of Central Africa beyond the fact that they contain many precious cabinet woods, dyewoods, etc.

CENTRAL AND SOUTH AMERICA.

MEXICO.

FOREST AREA.

The area of the forests of Mexico is estimated at from 20,000,000 to 25,000,000 acres of commercially valuable timber, or 5.1 per cent of the land area. The forest area per capita is 1.8 acres. The bulk of the forests apparently belongs to the Government, which works the forests on a system of leases.

COMPOSITION.

The forests of Mexico are of two distinct kinds: The tropical forests along the coast of the Gulf of Mexico, composed of mahogany, Spanish cedar, rosewood, and other fancy woods, and the pine and oak forests of the mountains, principally in the Sierra Madre on the Pacific side of the Mexican plateau.

Of these two types, the pine forest is by far the more important from the standpoint of the timber trade. These forests are very inaccessible, however, and little is known about the character of the timber, though some idea can be gained from the fact that a tract of 1,000,000 acres, recently sold, was estimated to have a stand of 8,000 board feet per acre, composed two-thirds of pine and one-third of oak. This is probably somewhat above the average for the whole area of pine forest.

The species found in the pine forests are known as white, sugar, and yellow pines, red and white firs, and many species of red and white oaks.

ANNUAL CUT, GROWTH, AND CONSUMPTION.

The forest resources of Mexico have been very little developed as yet; the pine timber is very inaccessible and the tropical hardwood forests have been worked only to a limited extent for mahogany and cedar. Figures on the growth of the forests and the wood consumption are lacking. The annual cut of timber is given at 225,000,000 board feet of manufactured stock, or approximately 37,500,000 cubic feet of logs; and it is estimated that Mexico imports 70 per cent of its timber consumption. Assuming that this is correct, the home consumption of manufactured stock, including ties, would be 125,000,000 cubic feet, or 9 cubic feet per capita. This low consumption is due to the still undeveloped resources of the country. Whether Mexico will be able to supply its own needs of timber is questionable. At present its imports are more than three times what is cut at home. Ninety-nine per cent of all the imports come from the United States.

WOOD PRICES.

The stumpage price for pine, in the remotest and least accessible portions of the country, is as low as 75 cents per thousand feet. Standard-gage pine ties sell at 45 cents and oak ties at 57 cents apiece delivered at the railroad. Green lumber from the saw is sold at from $17.50 to $32.50 per thousand feet b. m.

Mahogany and cedar logs shipped from Gulf of Mexico points f. o. b. New York command the following prices: Laguna cedar (*Cedrella odorata*), $45 to $60 per thousand board feet; Laguna mahogany (*Swietinia mahagani*), $40 to $55; cedar from other points, $32.50 to $57.50; mahogany from other points, $30 to $50.

CENTRAL AMERICA.

The five Central American Republics possess extensive forest areas, which, however, are so little explored that there are no data as to their extent or volume. In countries which do not know even the size of their population it is unreasonable to expect any knowledge of their forests. The reason for the existence of large forest areas in Central America is not due in any way to the care of them by the people, but to the fact chiefly that they are inaccessible on account of lack of roads or any other means of transportation.

SOUTH AMERICA.

According to Semler,[a] South America has an enormous forest wealth. With the exception of the prairies of Uruguay and Argentina, most of the continent is covered with forests. The whole chain of the Andes Mountains is wooded, the forests, according to altitude, latitude, and exposure, being of different composition. The cutting has not as yet impaired their value, because, first, the countries of South America are still very thinly settled; and second, which is more important, there are comparatively few rivers suitable for transporting timber to the coast. Not a single State has made any forest survey or has any clear idea of its forest resources.

The eastern coast of South America, south of Rio de la Plata to the Straits of Magellan, is extremely sparsely wooded. Only here and there are found a few thorny acacias, and along the rivers individual groups of willows, and occasionally antarctic beech, forms larger stands. In remarkable contrast to these are the islands of Tierra del Fuego, which, according to Darwin, are completely covered with forest.

North of the Rio de la Plata in Uruguay one finds small forests along the rivers, which have no commercial value, but which supply the needs of the few people who live there.

An entirely different picture is presented in Paraguay, whose slopes toward the Parana River are covered with almost impenetrable forests. On the slopes toward the Paraguay River are the settlements; here is open grass land, and only the hills, as a rule, are wooded. According to a statement, which, however, needs confirmation, there are seventy kinds of woods which are commercially useful, two of which, lapacho and quebracho, were used by the Jesuits in constructing their missions and are still well preserved in the ruins. Fifteen kinds of trees yield dyewoods, and eight yield fibers.

---

[a] Tropische und Nordamerikanische. Waldwirtschaft und Holkunde—Heinrich Semler, Berlin, 1888.

The forests of Brazil cover an area equal to one-half of Europe. The Amazon flows for a distance of 1,860 miles through a virgin forest which stretches 1,100 miles from east to west and 750 miles from north to south, and occupies an area of 825,000 square miles. Many of the Brazilian woods have excellent properties. The following are among the most valuable: Pernambuco (*Cæsalpinia echinata*), fustic (*Macluria tinctoria*), both of which occur only near the coast; Jacaranda, ironwood (*Cæsalpinia ferrea*), and cedar (*Cedrela brasiliensis*). The forests yield other valuable products, as rubber, Brazil nuts, Paraguay tea, guarana, gums, and resins.

Guiana is relatively just as rich in forests as Brazil, especially British Guiana, which has the advantage of four large rivers which, with their tributaries, are very suitable for floating logs. For this reason the exploitation of these forests has advanced further than in any other part of the country. British Guiana furnishes two of the most valuable trees for shipbuilding—greenheart (*Nectandra rodeæi*) and mora (*Mora excelsa*). Greenheart is the more important, and is so hard that it nicks the axes of choppers and will last for over one hundred years in water. Dutch Guiana has a very important wood in the purpleheart (*Copaifera bracteata*), which is suitable for the use of wheelwrights. French Guiana has a very important wood, so-called violet wood (Bois violette—*Copaifera bracteata*), which is especially suited for woodworking.

Venezuela is for the most part a prairie. Its most extensive forests are found on the lower course of the Oronoco River. The home production hardly exceeds the home consumption, the only wood that is exported being *Zygophillum arborea.*

Colombia, though partially a prairie State, possesses more forests than Venezuela. The exports, however, are insignificant because of lack of transportation facilities. Ecuador and Peru are in the mountain region of the Andes, and have exceptionally luxurious and extensive forests, which are, however, entirely inaccessible. Both of them import wood from North America.

The northern part of Chile has no forests. Forests are found only in the south, beginning at San Jago, especially in the provinces of Arauco, Valdivia, and Chiloé, but are rapidly disappearing, not on account of any great drain upon them for home consumption or export, but because the land is needed for agriculture. The forests are burned and treated by the people as an enemy, as was the case in this country at the time of the earliest colonization.

While at present South America imports some timber, it is hardly to be expected that these imports will greatly increase in the future. On the contrary, they will probably decrease, as the forests become opened up and are made more accessible.

WEST INDIES.

Semler takes a very gloomy view of forest conditions in the West Indies. He thinks that on the whole the West Indies present a sad picture of forest destruction. The small islands are robbed of their former forest wealth; and the large ones, like Jamaica, San Domingo, and Cuba, have only remnants. What little is left is almost entirely in the hands of private individuals, and nothing is done for the preservation of the forests.

John T. Rea,[a] who lived for four years in the West Indies, takes a more optimistic view of the situation, and since his observations are more recent and many of them are original they are apparently more trustworthy than Semler's. According to Rea's statement, two-thirds of most of the West Indian islands are still in virgin brush and forest, which are capable of yielding a plentiful supply of good material. Thus the Layon and Sara flats, or crown lands of Dominica, have an area of 40 square miles, and contain a mine of wealth in timber. In Trinidad, he estimates that there are at least 300,000 acres of forest land.

The total area of the West Indies is about 100,000 square miles. The trees on the whole are not very large, and yield as a rule only small scantlings. Some of the woods are useful for building and engineering work, but they are valuable principally for furniture, paneling, cabinet, and other fancy work. The immense variety of small articles, such as knife handles, knobs, buttons, etc., which are now manufactured from choice grained woods, opens a ready market for many West Indian timbers, the beauty of which can not be surpassed. Gum and resin yielding trees abound, and commercially valuable fibers may be stripped from quite a number of them. The bark, leaves, and berries of others furnish well-known drugs, dyes, and spices. Owing to the fact that all the best timber is in the inland forests with few convenient rivers for floating it down, and owing also to the defective character of the means of communication and the absence of sawmills and machinery for their treatment, the native woods have until lately been available only in small quantities. Circular and other rapid saws have been added to the plant of most of the public work yards, so that some of the disabilities have been remedied.

Little definite information is to be had concerning the forest area of Cuba. It probably does not exceed 5,000,000 or 6,000,000 acres, which, with a population of 2,050,000, makes the area per capita about 3 acres, and constitutes about 20 per cent of the total land area. Such an area with the small local demand for wood, if the forests are properly managed and cared for, certainly ought to furnish a sufficient supply for home consumption. Unfortunately, however, the forests do not contain the kinds of timber needed for most purposes, and hence large quantities are imported annually.

FOREST RESOURCES OF THE UNITED STATES AND HOW THEY COMPARE WITH THOSE OF OTHER COUNTRIES.

A detailed discussion of the forest resources of the United States is taken up under several other topics in the report to the commission. Here it is intended merely to compare the most important features of the forest resources of this country with those of other countries. This, perhaps, will serve at the same time as a summary of the statistical facts brought out in the preceding pages.

---

[a] The Indian Forester, Dec., 1902, p. 44a, "West Indian Timbers."

FOREST AREA.

The United States occupies the second place among the nations of the world as to the extent of its forests; Russia, European and Asiatic, comes first; Canada stands third.

The forests of the United States, according to ownership, may be roughly divided as follows: National forests, 100,000,000 acres, or 18.35 per cent; state forests, 3,000,000 acres, or 0.55 per cent; and private and unreserved public forests (unclassified), 442,000,000 acres, or 81.1 per cent.

The bulk of the forests is either in private hands or likely to pass into private ownership.

While government and state ownership of forests has invariably proved the most advantageous form, yet the proportion of forest land owned or controlled by the State can not always be taken as a criterion of the state of development of forestry in the country. The Government may, for historic or economic reasons, have only a small area of its own, but still exercise a great influence over the forests of other owners. Thus, Austria has only 10.7 per cent of the total forest area under state ownership, Switzerland 4.6 per cent, France 12 per cent, and yet forestry in those countries is at a high state of development, as all other forests are under direct control of the State, which practically amounts to management by the State.

Government and state forests comprise about 19 per cent of all forests; since the bulk of the forests is in private hands and entirely outside of state supervision, the area which is assured of a proper and careful management is comparatively small. Below is given a comparative table of forests under state ownership in the different countries of the world:

Percentage of forests under state ownership.

Country.	Per cent.	Country.	Per cent.
Great Britain	2.2	Norway	28.5
Italy	4.0	Bulgaria	29.6
Switzerland	4.6	German Empire	31.9
Belgium	4.8	Sweden	36.5
Portugal	8.0	Servia	36.6
Austria	10.7	Roumania	40.0
Croatia and Slavonia	11.0	Finland	61.2
France	12.0	European Russia	69.0
Hungary	15.0	Bosnia and Herzegovina	78.6
Denmark	23.8	Spain	84.0
United States (National and State)	18.9		

To supplement this table, it may be added that in the German Empire 66 per cent of the total forest area is under state control. In Austria, Hungary, France, Switzerland, Italy, Sweden, and Denmark the private forests are under state control; and for this reason the forest area under state supervision is much larger than the figures in the above table would indicate.

The forests of the United States form less than 29 per cent of the entire land area. The following table gives the forest area and percentage of the entire land area under forests, by States and Territories. The forest area per inhabitant is about 8 acres, corresponding closely to that in Sweden and Norway.

Forest area of the United States, by States and Territories, 1908.

State or Territory.	Land area (acres).	Forest area.	
		Acres.	Percentage of land area.
Alabama	32,818,560	20,000,000	61
Arizona	72,857,600	14,000,000	19
Arkansas	33,616,000	24,200,000	72
California	99,896,880	24,000,000	24
Colorado	66,341,120	12,000,000	18
Connecticut	3,084,800	1,000,000	32
Delaware	1,257,600	350,000	28
Florida	35,111,040	20,000,000	57
Georgia	37,584,000	22,300,000	59
Idaho	53,618,560	20,000,000	37

Kansas	52,335,360	1,000,000	2
Kentucky	27,715,840	10,000,000	36
Louisiana	29,061,760	16,500,000	57
Maine	19,132,800	14,900,000	78
Maryland	6,362,240	2,200,000	35
Massachusetts	5,144,960	2,000,000	39
Michigan	36,787,200	15,500,000	42
Minnesota	51,749,120	15,500,000	30
Mississippi	29,671,680	17,500,000	59
Missouri	43,985,280	18,300,000	42
Montana	93,296,640	18,000,000	19
Nebraska	49,157,120	800,000	2
Nevada	70,285,440	5,000,000	7
New Hampshire	5,779,840	3,500,000	61
New Jersey	4,808,960	2,000,000	42
New Mexico	78,401,920	12,000,000	15
New York	30,498,560	12,000,000	39
North Carolina	31,193,600	19,600,000	63
North Dakota	44,917,120	600,000	1
Ohio	26,073,600	4,800,000	18
Oklahoma	44,424,960	8,000,000	18
Oregon	61,188,480	27,000,000	44
Pennsylvania	28,692,480	9,200,000	32
Rhode Island	682,880	250,000	37
South Carolina	19,516,800	12,000,000	61
South Dakota	49,195,520	1,200,000	2
Tennessee	26,679,680	15,000,000	56
Texas	167,934,720	30,000,000	18
Utah	52,597,760	6,000,000	11
Vermont	5,839,360	2,500,000	43
Virginia	25,767,680	14,000,000	54
Washington	42,775,040	25,000,000	58
West Virginia	15,374,080	9,100,000	59
Wisconsin	35,363,840	16,000,000	45
Wyoming	62,460,160	10,000,000	16
Total	1,903,423,360	544,400,000	29

COMPOSITION.

The species which are most valued in international trade are the conifers, such as pine, spruce, hemlock, fir, and larch. Coniferous forests, on the whole, as German experience has shown, produce a larger percentage of structural timber than hard woods. In Germany, therefore, there is a tendency to increase the area under conifers at the expense of that under hard woods. This tendency is also often prompted by necessity. Hard woods, as a rule, require better soil than conifers, and in countries where there is need for more agricultural land to provide for an increasing population, the forests are more and more relegated to the poorer soils where conifers can be grown to better advantage than hard woods. The forest wealth of a country is therefore determined not only by the extent of the forest, but also by the species that make up the forest. As has already been pointed out, the richest forest, from a commercial standpoint, is that of Sweden, which consists chiefly of but two species, pine and spruce. In this country, as a result of the reckless cutting of conifers, especially in the northeastern States, and of repeated fires, thousands of acres of coniferous forests in New England have been converted into poor hard-wood forests. In the Catskills one finds thousands of acres originally covered by hemlock now under scrubby hard woods, and the same is true in Maine and New Hampshire. If the soil is at all suited to hard woods, they are favored in reckless cutting and burning because of their sprouting capacity. Thus, while Germany has increased its area of coniferous forests, the area of hard-wood forests in this country has probably increased at the expense of the coniferous forest area. Below are given the countries and the predominance of either hard woods or coniferous forests:

Distribution of hard woods and conifers, by countries.

Hard woods predominate.	Conifers predominate.	Hard woods predominate.	Conifers predominate.
Australia and Oceania.	Russia.	Spain.	Germany.
British India.	Finland.	Portugal.	Austria.
Hungary.	Canada.	Italy.	Switzerland.
Croatia and Slavonia.	United States.	British Isles.	
France.	Sweden.	Holland.	
Japan.	Norway.	Denmark.	

It is hard to tell what proportion of the total forest area of the United States is under hard woods. From the rather conflicting estimates of the present stand of conifers and hard woods it would seem that the proportion of conifers to hard woods by volume is about 4 to 1 (on the basis of Doctor Fernow's estimate of 2,000,000,000,000 feet b. m. of both kinds, and the estimate of 400,000,000 feet b. m. of hard woods by the American Lumberman).

Of all the countries of the world the United States is the only one which has such a variety of conditions as to favor the growth of a great number of valuable species, both conifers and hard woods, over large areas.

PRESENT STAND.

The latest and best estimate of the stumpage of the United States places it at 2,500,000,000,000 feet b. m. This, however, does not represent the forest capital in the sense in which does the estimate of 944,700,000,000 board feet of the German Empire. In Germany the estimated stand is a constant quantity, a capital, which is capable of producing annually some 50 cubic feet per acre. In this country the stumpage represents a capital which is annually drawn upon, since the cut does not represent the annual growth but exceeds it. With an annual cut of about 23,000,000,000 cubic feet of standing timber and a forest area of about 545,000,000 acres, the cut per acre is 42 cubic feet, while the annual growth on the area has been estimated at 12 cubic feet per acre.

The United States is not the only country which at present cuts more than is annually produced. The different countries may be divided according to whether they cut more than the forest produces, less, or just the same amount. In the following table are brought together the data available from the different countries of the world concerning the annual cut and the annual growth per acre.

Annual cut and annual growth per acre, in cubic feet, for various countries.

	Annual growth.	Annual cut.
Countries which overcut.		
Austria	42.4	60-67 } 53.00
Hungary	44.4	30-33

British India	....	3.00
Japan	....	35.00
Servia	....	....

[a] Plus great fire loss, estimated at 170 cubic feet per acre.

[b] No definite figures on these countries, but facts indicate that they are being overcut.

[c] State forests, 38.7 per cent.

[d] Private forests, 61.3 per cent.

While in a general way these figures indicate the annual cut and growth in the different countries, yet they do not tell the whole story. They represent the total amount of wood cut and produced, irrespective of kind.

In most of the countries where at present the forests are being overcut, and they are the countries which still contain virgin timber, the proportion of structural timber to firewood in the cut is much greater than will be the case in the second growth. The figures would indicate that out of 23,000,000,000 cubic feet of wood cut annually to supply the forest products, 9,000,000,000 feet (allowing 90 cubic feet per cord), or 39 per cent, is firewood. This percentage of firewood appears to us too high, but if it is correct, then the proportion of saw-log timber in the second cut will certainly be less than half of the total amount of wood produced annually, because the forests under the present system of cutting do not improve, but deteriorate in quality. This holds true not only of the United States, but of Canada, Austria, and Norway, while the reverse is true of countries like Germany and France, where the percentage of saw-log timber is gradually increasing through proper methods of management.

The cut per acre in such countries as Canada, the United States, and Russia does not represent the actual cut per acre, because these figures do not always refer to the actual productive forest area, but include a great deal of unproductive land, such as swamps, burns, etc. If the figures referred only to the productive-forest area, if that could be known, the cut per acre would be much higher.

On the whole, the figures of annual cut and growth show a sad state of affairs. Countries which with proper care for their forest resources could continue to be a source of timber supply to many other countries deficient in wood are, with a few exceptions, overcutting their forests and rapidly deteriorating them, and in those few countries with large forests which do not overcut the resources are deterred only through want of capital or lack of natural means of transportation, such as rivers, etc. On the other hand, some other countries, though they have not enough forests to supply their own needs, continue to deplete what little they possess.

From the figures of annual growth and cut in the United States it would appear that the cut is more than three times the growth. In point of fact, however, the depletion of our forests goes on much more rapidly, owing to loss by fire on account of the lack of protection given the forests.

ANNUAL CONSUMPTION.

The consumption of wood is different in different countries, being dependent on the industrial development, on the presence of coal for fuel, and of substitutes for structural timber. In the following table are brought together the total annual consumption and the consumption per capita in the various countries of the world:

Annual and per capita consumption, in cubic feet, of various countries.

Country.	Total annual consumption.	Consumption per capita.		
		Total.	Timber.	Firewood
United States	23,000,000,000	260.0	160.0	100.0
Canada	1,111,209,625	192.0	60.0	132.0
Norway	276,000,000	125.0		
Sweden	404,000,000	120.0		
Finland	237,000,000	91.5		
Russian Empire (exclusive of Finland)	6,576,280,000	63.0	25.0	38.0
Austria-Hungary	2,500,000,000	57.0	28.5	28.5
Switzerland	117,000,000	38.0	15.7	22.3
Germany	2,064,122,300	36.6	18.8	17.8
Japan		30.0		
France	954,640,000	24.6	6.9	17.7
Denmark	48,826,500	19.8		
Belgium	119,604,126	17.7	10.8	6.9
United Kingdom	670,890,000	14.0	12.8	1.3
Holland	67,200,000	13.1	10.3	2.8
Italy	405,548,000	13.0	2.5	10.5
British India	236,611,600	.8+		

Thus the home consumption of the United States is larger than that of any other country in the world. While the exports amount to 2,600,000,000 feet b. m., the imports in 1907 were 1,700,000,000 feet b. m., or an excess of exports over imports of only 900,000,000 feet b. m., or 150,000,000 cubic feet, a practically insignificant amount. Therefore, the annual cut of 23,000,000,000 cubic feet may be taken as the home consumption of the United States.

WOOD PRICES.

There is a certain relationship between the wood prices of a country and the care which the forests receive. In countries with large forests and sparse population, wood prices are low and there is very little forest protection. In the following table are given wood prices on the stump for some leading European countries and for the United States.

Wood prices on stump in various countries.

Species.	Price of structural timber per cubic foot.			
	United States, 1907.	Prussia, 1902.	Wurttemberg.	Hungary, 1901.
Oak	$0.04	$0.14	$0.25	$0.038-$0.11
Beech	.02	.084	....	.067
Spruce [a]	.033	.096	....	....
White pine [b]	.05	.078	.13	.034- .067

Species.	Price of cordwood per cord.			
	United States, 1907.	Prussia, 1902.	Wurttemberg.	Hungary, 1901.
Oak	$1.00	$4.68	....	$0.60-$3.20
Beech	1.00	4.68	$8.28	1.31- 2.60
Spruce	....	2.97	....	....
Pine	.75	3.33	6.12	....

[a] Eastern spruce only.

[b] Eastern white pine.

These figures simply give an idea of the relative value of wood in different countries. A comparison of wood prices is extremely difficult, because prices do not always include the same items. In some countries the prices include transportation to points of shipment, in others they refer to partly finished products, etc. The few figures given in the above table all refer to the price on the stump. The stumpage prices for the United States are taken from Bulletin 77, page 40, Forest Service, and 167 cubic feet are assumed to equal 1,000 board feet. The prices in the United States are mainly those in the East, and are probably higher than if western species were chosen. As it is, oak timber, probably much poorer in quality than the white oak in this country, brings in Prussia over three times as much on the stump, and in Wurttemberg over six times as much as here. The same holds true for other species, except white pine, which in New Hampshire and the Northeast is at present bringing prices approaching those obtained by Scotch pine in Prussia and Hungary. In Wurttemberg, however, Scotch pine brings close to three times as much as white pine in this country. The prices for cord wood in European countries are also much higher than in this country. We excluded cord wood of spruce and pine in this country, since they are used for pulp, and it would not be fair to compare them with wood used for firewood in other countries.

The difference in the wood prices here and in European countries is very great indeed, but still they do not show the actual difference in the value obtained from timber in this and other countries. These figures refer only to the used part, which is much greater in Europe than here, and therefore the difference between the stumpage value per tree obtained in this country and abroad must be still greater.

Part II.—HOW FAR CAN WE COUNT ON FOREIGN SOURCES OF SUPPLY?

SUMMARY.

It is obvious that if the forest resources of the United States fail we must increase our imports of wood from other countries. It is equally obvious that if the net imports of the present wood-importing countries are increased, they will compete with the United States for wood from other countries. This will necessitate a still greater output of timber from wood-exporting countries. With these considerations in mind concerning the timber trade of the principal wood-producing and wood-using countries of the world, we reach the following conclusions:

EUROPE.

Europe both imports and exports more than one billion cubic feet of wood yearly. The imports, however, exceed the exports by about 10 per cent, the excess being made up chiefly by supplies from Canada and the United States. A brief summary of European conditions is as follows:

First. The leading import countries—that is, Great Britain, Germany, France, Belgium, Switzerland, etc., are rapidly increasing the amount of their imports, and this increase is certain to continue.

Second. Russia, Finland, and Sweden only of the export countries have increased their exports to great extent without encroaching on their timber capital.

Third. Norway and Austria-Hungary are already overcutting their forests and will in all probability have to reduce their exports in the future.

In view of these facts and considering the rising prices of wood throughout the world, it is certain that any increase of wood exports from Russia, Finland, and Sweden will be eagerly competed for by Great Britain, France, and Germany, and also that there will be no surplus of any consequence for the United States, which is handicapped by its greater distance from the principal source of supply.

AFRICA.

Both north and south Africa are importers of timber and these imports will increase with the increased development of the country. The forests of central Africa are little known, but it is certain that their area is not so great as was once commonly supposed. The chief species of commercial value in that section are hard woods, which are expensive, and which have little bearing on the question of the supply of common timber for use in the United States.

ASIA.

India, the chief forest country of Asia, exports teak and some other valuable woods, but it is necessary for it to import structural timber. China is a wood-importing country, and its requirements will undoubtedly take the most of any surplus that may come from eastern Siberia and Manchuria. If only structural timber is considered, Japan is a wood-importing country, but if all woods are considered, it is a wood-exporting country. Japan can supply its own needs when all the forests become accessible, but will probably not be able to export any saw-log timber.

AUSTRALASIA.

Australia is a wood-importing country at present, and it is not likely that there will ever be much surplus timber for export. With the exception of comparatively small quantities of hard woods, the forests of Hawaii can never become important in the timber trade of the world. The Philippines at present import much more timber than is exported. Eventually the native forests should supply the principal demands of the home market with a considerable excess for exportation to near-by countries, such as China. The total stand of commercial timber in the Philippines, however, is no greater than the amount of timber annually cut for lumber in the United States. Hence the islands will never become an important factor in supplying our needs for wood.

TROPICAL AND SOUTH AMERICA.

Mexico, the West Indies, and Central America now import timber, not so much because they have none, but for the reason that their stands are at present inaccessible. It is probable that they will for some time continue to import the common structural timbers and will export valuable woods, such as mahogany and cedar.

For many years South America will continue to export hard wood, dye wood, etc., and to import lumber and construction material. When the great forests of the Andes and the interior are opened up then they will supply the home market. Wood consumption will have so increased in South America by that time, however, and logging and transportation will be so expensive because of the comparative inaccessibility of the forests, that it is not reasonable to expect any considerable exportation of timber suitable for common uses in the United States.

NORTH AMERICA.

The total stand of timber in Alaska is probably no greater than twice the amount of lumber annually cut in the United States. The Alaskan industries require a considerable proportion of the output of the home forests, so little will remain for export to the United States.

Canada is the only country from which the United States is importing any considerable amount of timber. The total amount of standing timber in Canada, however, is estimated at no more than one-quarter of that in the United States. The Canadian forests are probably being cut and burned faster than they are growing, and this, with the rapid development of the Canadian provinces, will require all that the forests will eventually produce.

CONCLUSIONS.

A review of the timber trade of the various timber countries of the world shows a steady increase in the wood consumption and imports of nearly all of the leading countries, and but three important countries, Russia, Finland, and Sweden, can increase their exports without reducing their forest capital. This increase will be needed in western Europe to make up the growing deficit there and will not be a source of supply for the United States.

The tendency is toward a greater cutting of timber by the wood-exporting countries to make up the increasing deficit of the wood-importing countries. This policy, if continued, would lead to a universal shortage with no surplus to draw upon. There is no doubt, however, that there is enough accessible actual and potential forest land in the civilized countries of the world to produce, under proper management, an abundance of timber to supply indefinitely the world's growing demand.

This country must, so far as possible, depend upon itself. A considerable proportion of the present forest area of the United States will undoubtedly be cleared for agriculture as the population increases. The area of land in the United States so situated as to be permanent forest land is about 400,000,000 acres. The inevitable increase in wood consumption, following the increase in population and growth of industries, will thus have to be supplied from the diminished forest area. This means that the land should be surveyed and classified by the Government as permanent forest land before it is too late.

INTRODUCTION.

After the above-detailed discussion of the forest resources of the various countries of the world, the question naturally arises, How far, in case our own resources fail, can we count on foreign sources of supply? It is obvious that there must be an increase in exports of some countries, in event of a failure of our timber supply, to make up our deficiency. It is equally evident that if the amount of net imports of present importing countries should increase, they would compete with the United States in case it should run short, and thus necessitate a still greater output of timber by the exporting countries.

It is important, therefore, to trace the tendencies of the timber trade of the various countries for the last few years to see what deductions can be drawn as to the future, bearing in mind their resources, as brought out in Part I, and trying to bring out the reason why they import or export. The following table[a] shows the amount of net exports or imports of the important countries of the world:

Net exports and imports of various countries, yearly average, 1897–1901.

Country.	Net exports.		Net imports.	
	Cubic feet.	Feet board measure.[a]	Cubic feet.	Feet board measure.[a]
Russia (with Finland)	295,000,000	2,300,000,000		
Sweden	223,000,000	1,784,000,000		
Austria-Hungary	183,500,000	1,460,000,000		
Canada	107,200,000	857,600,000		
Norway	52,000,000	416,000,000		
United States	51,000,000	408,000,000		
Roumania	3,000,000	24,000,000		
India	2,750,000	22,000,000		
West coast of Africa	1,300,000	10,400,000		
West Indies, Mexico, Central America	650,000	5,200,000		
Alaska			170,000	1,300,000
Japan[b]			250,000	2,000,000
Ceylon			500,000	4,000,000
Servia			750,000	6,000,000
Mauritius			1,000,000	8,000,000
Greece			1,750,000	14,000,000
Philippine Islands			2,000,000	16,000,000
Bulgaria			2,500,000	20,000,000
China			2,500,000	20,000,000
Natal			2,500,000	20,000,000
Portugal			3,000,000	24,000,000
Cape of Good Hope			7,500,000	60,000,000
Australia			8,000,000	64,000,000
Switzerland			8,500,000	68,000,000
Holland			9,000,000	72,000,000
Egypt			10,000,000	80,000,000
Spain			10,500,000	84,000,000
South America			16,500,000	132,000,000
Italy			21,000,000	168,000,000
Denmark			23,500,000	188,000,000
Belgium			51,000,000	408,000,000
France			61,500,000	492,000,000
Germany			230,000,000	1,840,000,000
British Isles			464,500,000	3,716,000,000

[a] Since the figures include lumber, logs, poles, and split wood, 1 cubic foot was regarded as equivalent to 8 board feet. In the original conversion from tons, 1 ton is regarded as equivalent to 50 cubic feet.

[b] Schlich includes only construction timber; judged by value. Japan is an exporting country.

The relation between forest area per capita and export or import of timber can be seen from the following table:[b]

It will be noticed that countries with 92 or more acres per 100 inhabitants have a surplus of exports over imports, while those with 85 acres or less have a surplus of imports over exports.

---

[a] Schlich: The Outlook of the World's Timber Supply.

[b] Zon: The Future Use of Land in the United States.

Relation between forest area per 100 inhabitants and exports and imports of the different countries.

Country.	Forest land per 100 inhabitants.	Excess of exports over imports.[a]	Excess of imports over exports.[b]
Exporting countries.	*Acres.*		
Canada	2,400	$26,551,000	
Finland	1,850	14,970,000	
Sweden	952	34,770,000	
Norway	702	9,585,000	
United States	620	13,450,000	
Russia (Europe)	462	23,039,000

Netherlands	10		5,945,000
Great Britain	7		93,950,000

[a] Average for five years, 1895–1899.

[b] Timber land largely in mountains and difficult of access. These countries will in time become exporters instead of importers.

DIVISION INTO EXPORTING AND IMPORTING COUNTRIES.

Since there are more statistics available for the countries of Europe than for others, they are first considered in detail in the order in which they occur in the following outline:

1. *Import countries.*—These may be subdivided into the four following groups, according to the reasons for their being import countries:

(*a*) Countries which, with a highly developed forest management and important forest possessions, themselves produce much wood, but in spite of this, on account of their important industries, can not do without foreign wood: German Empire, France, Switzerland, Belgium.

(*b*) Countries in which forest management plays but a small part on account of the small forest area: Great Britain, Netherlands, Denmark.

(*c*) Countries with only slightly developed forest management and little wood consumption: Italy, Spain, Portugal, Greece.

(*d*) Countries with relatively large forest areas, which, however, are in large part not yet fully developed, unequally distributed, or poorly managed: Servia, Turkey, Bulgaria.

2. *Export countries.*—These are Russia (with Finland), Sweden, Norway, Austria-Hungary (with Bosnia-Herzegovina), and Roumania.

IMPORT COUNTRIES.

EUROPE.

GERMAN EMPIRE.

Germany is unable to produce enough timber to satisfy its needs, and there is no doubt this condition will continue in the future.

Since 1863 the imports have exceeded exports, and the difference between them has been growing steadily, as shown in the two following tables.

It is worthy of note that since 1899 Austria-Hungary has taken Russia's place as the chief wood supplier of Germany. This is largely due to the greater development of the sawmill industry in Austria-Hungary, and to the fact that railroad communication is much better. Russia exports nearly all material by water.

If the average yearly import of the period 1880–84 is taken as a standard equal to 100, then imports have increased as follows:

Total timber imports and exports of Germany.[a]

Year average of—	Imports.		Exports.		Excess of imports.	
	Tons.[b]	Value.	Tons.	Value.	Tons.	Value.
1862-65	1,314,000	....	1,181,000	....	133,000	....
1866-71	1,963,000	....	879,000	....	1,084,000	....
1872-75	3,633,000	....	1,153,000	....	2,480,000	....
1876-78	3,190,000	$43,875,000	1,183,000	$17,500,000	2,007,000	$26,375,000
1879-84	1,990,000	22,400,000	731,000	10,000,000	1,259,000	12,400,000
1885-87	2,253,000	22,400,000	501,000	6,425,000	1,752,000	15,975,000
1888-96	3,051,000	36,575,000	302,000	4,050,000	2,749,000	32,525,000
1897-1901	4,637,000	63,800,000	329,000	5,550,000	4,308,000	58,250,000
1902	3,932,000	46,400,000	342,000	5,575,000	3,590,000	40,825,000
1903	4,797,000	55,125,000	371,000	6,175,000	4,426,000	48,950,000
1904	5,049,000	59,475,000	323,000	5,825,000	4,726,000	53,650,000

[a] Endres: Forstpolitik.

[b] In this and the following tables 40 cubic feet is a fair equivalent for 1 ton.

Percentage of imports from most important countries which export to Germany.[a]

Year average of—	Russia.	Austria-Hungary.	Sweden.	United States.	Norway.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
1880-84	46.6	37.0	7.3	0.7	2.4
1885-87	40.8	34.6	8.1	.8	2.1
1888-96	47.4	33.4	10.9	2.4	1.6
1897-1901	37.8	42.1	10.6	5.9	1.2
1902	35.3	43.0	12.5	7.4	1.2
1903	37.5	41.1	10.6	7.5	1.0

[a] Endres, loc. cit.

Increase of exports, taking the period of 1880–1884 as a standard of 100.[a]

Year average of—	Russia.	Austria-Hungary.	Sweden.	United States.	Norway.
1880-1884	100	100	100	100	100
1885-1887	120	113	134	156	100
1888-1896	166	156	244	514	111
1897-1901	201	[a] 283	356	1,950	127
1902	180	245	350	2,000	109
1903	206	285	371	2,571	111

[a] Endres, loc. cit.

A glance at the above tables, with the knowledge that the forest resources of Germany are and have long been developed to their highest capacity, plainly indicates that Germany's imports will continue to rapidly increase. Her competition will be a large factor in bidding for any surplus timber in the future, and must not be lost sight of it in considering the possible sources of supply for the United States.

FRANCE.

A consideration of the following table shows that France will certainly continue to import, but the net imports are not appreciably increasing, since the population is about stationary, while the industries were already well established in 1875. The forest area is being extended, and coppice is being converted into high forest, so the imports will probably not increase to any extent for a number of years, but with growing industries they will certainly not decrease, and France will continue to be an important factor in competing for the surplus timber of the export countries.

Imports and exports of France.[a]

Year.	Imports.		Exports.		Excess of imports.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1875		$32,820,000		$8,280,000		$24,540,000
1880		55,600,000		6,960,000		48,640,000
1885		31,780,000		5,220,000		26,560,000
1890		31,580,000		8,580,000		23,000,000
1895		26,020,000		8,880,000		17,140,000
1900	1,658,000,000	35,400,000	1,123,000,000	9,920,000	535,000,000	25,480,000
1901	1,667,000,000	35,620,000	982,000,000	9,580,000	685,000,000	26,040,000
1902	1,584,000,000	33,820,000	935,000,000	9,320,000	649,000,000	24,500,000
1903	1,571,000,000	32,560,000	1,052,000,000	10,840,000	519,000,000	21,720,000
1904		33,480,000		10,780,000		22,700,000

[a] Endres, loc. cit.

France gets most of its sawn timber from Russia, Sweden, Norway, Austria, and America.

SWITZERLAND.

The following table shows that Switzerland, with its carefully managed and productive forests, is still increasing imports yearly with the development of industries, and must be reckoned with as a competitor in future bidding for timber.

Imports and exports of Switzerland.[a]

Year.	Imports.		Exports.		Excess of imports.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1878	180,000,000			$1,160,000		
1887	214,000,000					
1895	255,000,000	$2,580,000	54,000,000	380,000	201,000,000	$2,200,000
1900	273,000,000	3,160,000	64,000,000	520,000	209,000,000	2,640,000
1901	266,000,000	2,680,000	79,000,000	660,000	187,000,000	2,020,000
1902	278,000,000	2,840,000	77,000,000	640,000	201,000,000	2,200,000
1903	285,000,000	3,140,000	64,000,000	500,000	221,000,000	2,640,000

[a] Endres, loc. cit.

The percentage of firewood constitutes over half of the total import, most of which comes from southern Germany and France. The import of sawed material exceeds that of logs, most of which is imported from Austria-Hungary.

BELGIUM.

The net imports of Belgium are surprisingly large when the small area of the country is considered, and they are increasing at a rapid rate. In the future they will certainly continue to increase, and help swell the demand of western Europe for wood from foreign countries.

Imports and exports of Belgium.[a]

Year.	Imports.	Exports.	Excess of imports.
1870	$4,480,000	$520,000	$3,960,000
1880	11,600,000	2,200,000	9,400,000
1890	14,080,000	2,600,000	11,420,000
1896	18,300,000	....	....
1900	26,940,000	2,980,000	23,960,000
1901	26,520,000	2,800,000	23,720,000
1902	26,860,000	660,000	26,200,000
1903	[b] 27,980,000	580,000	27,400,000

[a] Endres, loc. cit.

[b] Represents 68,835,000 cubic feet.

Sweden is the chief source of imports; then come Russia, Germany, and France.

GREAT BRITAIN.

Great Britain, on account of its scarcity of forests, its highly developed industries, and its great coal production, imports more wood than any other country in the world. The English wood consumption has an influence on the lumber trade of the whole world, and also on the price of lumber; therefore the inevitable increase in it is of great interest to the United States, especially in view of the amount of imports from Canada.

Imports of Great Britain.[a]

Year.	Quantity.	Value.
	Cubic feet.	
1880	321,150,400	....
1890	300,236,500	$77,600,000
1900	496,247,400	125,464,000
1901	497,021,000	109,129,860
1902	498,516,400	122,156,960
1903	542,581,200	131,522,300
1904	458,900,000	....

[a] Endres, loc. cit.

The greatest imports are in sawed and hewed wood. Scandinavia furnishes one-third of the imports, Russia one-fourth, and America one-fifth. The export is practically nothing.

DENMARK AND NETHERLANDS.

These countries have such small areas in forest as compared with their population that imports of timber are certain to increase, as they have steadily done in the last few years.

ITALY.

The imports of Italy have slowly increased for some years, and the increase in population and development of industries will certainly more than offset any increased production of the forests, which are now mostly coppice and managed under a short rotation.

SPAIN, PORTUGAL, AND GREECE.

In spite of the fact that the industries of these countries are as yet scarcely developed, the forests can not supply the small consumption of wood. As mines and other industries are developed the imports must increase rapidly and help make the European deficit of timber much greater than at present, for the forest area per capita is extremely small.

TURKEY, BULGARIA, AND SERVIA.

These countries import timber in increasing amounts, although they are well wooded and industries are undeveloped. There is no question that their forest areas are sufficiently extensive to supply the home consumption were they under rational management and transportation facilities developed. But by the time these improvements are brought about, consumption will be much greater than at present, and the wasteful methods now in force will have greatly reduced the productive power of the forests. Considering the above facts, it seems safe to predict a continuation of the timber imports for some years at least.

EXPORT COUNTRIES.

EUROPE.

AUSTRIA-HUNGARY.

We come now to the exporting countries of Europe. Since the annual cut is greater than the annual growth, it is evident that the exports of Austria-Hungary must be reduced, for the forests are nearly all under careful management and their productivity can be increased only to a limited extent. As seen below the exports have steadily increased, and may continue to do so for some years, but not for long.

Wood export of Austria-Hungary.[a]

Year.	Exports.		Imports.		Excess of exports.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1880	1,746,000	$22,400,000	173,000	$1,150,000	1,573,000	$21,250,000
1885	2,258,000	31,600,000	223,000	1,750,000	2,035,000	29,850,000
1890	2,457,000	31,350,000	210,000	2,450,000	2,247,000	28,900,000
1895	2,398,000	32,850,000	156,000	1,850,000	2,242,000	31,000,000
1900	4,237,000	64,100,000	252,000	2,250,000	3,985,000	61,850,000
1901	3,903,000	55,650,000	268,000	2,200,000	3,635,000	53,450,000
1902	3,605,000	49,650,000	237,000	2,150,000	3,368,000	47,500,000
1903	4,238,000	58,700,000	267,000	2,300,000	....	....

[a] Endres, loc. cit.

Wood export of Austria-Hungary—Continued.

1903	54	17	10	....	2.9

RUSSIA.

The forests of Russia are capable of permanently producing much more timber than is now cut from them. In fact, the generally increasing deficit of wood in Europe must be met in large part from Russia. The following table shows how the exports of Russia have increased.

Russian exports to different countries.[a]

Year.	Tons.	Value.	Year.	Exported to—			
				England.	Germany.	Holland.	France.
				Per cent.	*Per cent.*	*Per cent.*	*Per cent.*
1885	....	$13,230,000	1894	50	24	9	8
1890	....	15,100,000	1895	46	28	8	8

1901	....	28,625,000	1901	43	30	12	7
1902	3,460,000	27,700,000					
1903	4,090,000	32,650,000					

[a] Endres, loc. cit.

Russia's imports are limited to the southern parts, and are mainly from Austria and Roumania. In 1901 the total imports were 756,600 tons, with a value of $4,560,000.

FINLAND.

Finland can no doubt increase her exports considerably, for the private forests cut but 0.2 of a cubic foot per acre more than the annual growth, while the 38.7 per cent of the forests which the State controls do not cut nearly so much as the growth. The following table shows the rapid development of the sawmill industry in recent years.

Development of the sawmill industry, by years.[a]

	1870.	1886.	1890.	1892.	1895.	1896.	1899.
Number of sawmills	132	245	341	376	427	464	460

[a] Endres, loc. cit.

In 1899, 248 sawmills were run by steam and 212 by water. Sixteen thousand workmen were employed.

Exports of Finland.[a]

1880	....	11,140,000	1903	211,800,000	26,200,000

[a] Endres, loc. cit.

SWEDEN.

Sweden's annual cut is less than the annual growth, and the forests may be expected to supply the home demands and allow the country to continue to increase exports to some extent. The following table shows the rate of increase in them of late years.

Exports of Sweden.[a]

Year average of—	Quantity.	Value.	Year average of—	Quantity.	Value.
	Cubic feet.			*Cubic feet.*	
1871-1875	116,490,000	$21,175,000	1897	246,750,000	$27,600,000
1876-1880	130,960,000	22,075,000	1898	236,160,000	36,600,000
1881-1885	161,670,000	24,125,000	1899	239,690,000	35,150,000
1886-1890	183,560,000	24,625,000	1900	245,690,000	38,450,000
1891-1895	210,040,000	28,275,000	1901	219,920,000	32,975,000
1896	235,800,000	32,975,000	1903	243,570,000	....

[a] Endres, loc. cit.

Great Britain takes about half of the Swedish exports, then come France, Denmark, Germany, Netherlands, Cape Colony, Australia, and South America. Planed boards go chiefly to Netherlands, Cape Colony, England, and Australia.

The large number of floatable streams in Sweden have been important factors in enabling it to take one of the foremost places in the world's timber market. The wood industry has been intensively developed. In 1898 there were 1,030 saw and planing mills, which employed 40,700 workmen; in addition there were 501 other woodworking establishments, with 22,300 workmen. As motor power, 507 turbines, 706 steam engines, and 178 electric motors were used.

NORWAY.

The forests of Norway are now being overcut, so that the exports, which have not increased much since 1870, will evidently decrease in the future.

Exports of Norway, by amounts and values.[a]

Year.	Quantity.	Value.
	Cubic feet.	
1870	67,211,000	....
1876-1880	64,964,000	....
1886-1890	65,517,000	$7,875,000
1895	59,128,000	6,900,000
1900	70,671,000	10,671,000
1901	63,717,000	8,900,000
1902	69,259,000	9,575,000
1903	75,260,000	11,125,000
1904	63,434,000	9,075,000

[a] Endres, loc. cit.

Exports of wood-pulp material are also very important, and in 1904 reached a value of $7,500,000.

The exports were distributed as follows:

Distribution of timber exports of Norway.[a]

Year.	South Africa.	Great Britain.	Belgium.	Nether-lands.	France	Germany.	Denmark.	Australia.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
1881	....	64.0	2.8	10.0	10.0	4.5	4.3	....
1887	2.0	63.4	7.2	6.6	8.6	4.3	2.1	3.3
1898	2.5	57.0	9.0	9.0	5.0	5.0	....	7.0
1900	2.1	63.0	8.4	6.1	4.9	4.5	1.9	5.9
901	3.0	63.0	7.4	4.9	5.5	3.9	1.7	6.6

[a] Endres, loc. cit.

A little goes to Sweden, Iceland, Spain, and Brazil.

ROUMANIA.

Satisfactory data as to the cut and growth of forests in Roumania can not be had, but the forest area per capita is too small to expect much increase in export in the future, although of late years it has grown rapidly, as transportation developed.

SUMMARY FOR EUROPE.

The following table shows the great increase in the export timber trade of the world's leading export countries.

Value of export timber trade of leading export countries.[a]

Country.	Average of years—					
	1881-1890.	1891-1895.	1896-1900.	1901.	1902.	1903.
Sweden	$27,100,000	$31,450,000	$40,675,000	$37,250,000	$38,750,000	$41,500,000
Norway	9,350,000	7,850,000	11,325,000	10,000,000	10,750,000	14,000,000
Finland	8,700,000	10,175,000	17,500,000	20,300,000	21,625,000	26,250,000
Russia	16,925,000	22,700,000	29,250,000	30,900,000	29,925,000	35,250,000
Austria-Hungary	23,875,000	25,800,000	42,500,000	47,300,000	42,200,000	49,900,000
United States	21,375,000	21,250,000	40,300,000	41,375,000	52,075,000	51,550,000
Canada	23,000,000	23,450,000	27,850,000	29,850,000	33,500,000	31,400,000
Total	130,325,000	142,675,000	209,375,000	216,975,000	228,825,000	249,850,000

[a] Endres, loc. cit.

In 1903 the total import of Europe was 1,164,900,000 cubic feet,[a] and the total export 1,023,700,000 cubic feet, showing an excess import of 141,200,000 cubic feet.

This balance is made up chiefly from Canada and the United States.

A brief summary of Europe leads to the following conclusions:

1. The leading import countries, Great Britain, Germany, France, Belgium, Switzerland, etc., are rapidly increasing the amount of their imports, and this increase is certain to continue.

---

[a] Endres, loc. cit.

2. Russia, Finland, and Sweden only of the export countries can increase to any great extent their export without reducing their timber capital.

3. Norway and Austria-Hungary are already overcutting, and will in all probability have to reduce their exports in the future.

In view of these facts, with the rising prices of timber, it is certain that any increased exports from Russia, Finland, and Sweden will be eagerly competed for by Great Britain, France, Germany, etc., and there will be no surplus of any consequence for the United States, handicapped as it is by greater distance, and hence greater cost for transportation. Hence in case of a failure of our timber resources, we must look to other than the European countries for a source of supply.

AFRICA.

EGYPT.

Egypt has no forests in the true sense of the word, but is interesting as a buyer. The industrial development and railroad building which the last few years have seen in Egypt, and which give every sign of continuing, will certainly result in increased demand for timber. The following table shows the important increase in it of late years.

Import of Egypt.

Year average.	Structural timber.	Firewood.	
		Quantity.	Value.
		Cubic feet.	
1885-1889	$1,547,000		
1890-1894	2,161,500	3,187,000	$220,000
1895	2,481,500	2,355,000	136,000
1896	2,122,000		
1897	2,506,500		
1898	3,170,500		
1899	3,213,500		

From A. A. Radzig, Forests and Forestry in Various Countries, A Statistical Investigation.

SOUTH AFRICA.

The forests of South Africa are entirely inadequate to supply home needs, and the imports are certain to continue to increase with the population and industrial development.

Imports of Cape Colony and Natal.[a]

Year.	Cape Colony.	Natal.
1890-1895	$575,500	$417,000
1895-1899	850,000	876 000

From A. A. Radzig, loc. cit.

These imports amount to 5,000,000 cubic feet, the annual average for the years 1895–1899. The following countries sent in 1895 to South Africa the amounts shown below:

Exports to South Africa.

Country.	Quantity.	Country.	Quantity.
	Cubic feet.		*Cubic feet.*
Sweden	2,465,777	India and Burma	56,679
Norway	1,041,[illegible]	New Zealand	32,548
United States	1,020,14[illegible]	South Africa	1,582
Great Britain	185,121		

From B. P. Mrozovski, Brief Review of Lumber Industry.

CENTRAL AFRICA.

The forests of Central Africa are little known, but their area is not so great as commonly supposed, and the chief species of commercial value are expensive hard woods, which have no bearing on the question of the supply of common timber for the United States.

NORTH AFRICA.

The countries of North Africa, other than Egypt, have barely sufficient forest for the low home consumption, except Algeria, which has already had to import timber. With increased railroad building and general development this import will increase.

Imports of Algiers.

Year average.	Value.
1890–1894	$813,500
1895–1899	814,000

From B. P. Mrozovski, Lumber Industry.

A review of Africa shows, then, a timber import destined to increase in the future in all but the central part, which is utterly undeveloped and can export only costly woods.

ASIA (EXCLUSIVE OF SIBERIA).

CHINA.

The reasons why China will continue to import in rapidly increasing amounts have been fully brought out; that it will take the surplus of eastern Siberia and continue to draw on the United States and Canada is certain.

Imports of structural timber of China.

Year average.	Value.	Year average.	Value.
1867–1870	$261,500	1885–1889	$744,000
1871–1875	440,500	1890–1894	1,074,500
1876–1879	616,500	1895–1899	1,201,000
1880–1884	592,000		

From B. P. Mrozovski, Lumber Industry.

PERSIA.

The forests of Persia are limited in extent and do not produce woods of common use to an extent to supply any timber for export.

CEYLON, STRAITS SETTLEMENTS, INDO-CHINA, ETC.

These minor countries of Asia are too little known and their forests are too little explored to give any basis for definite predictions. However, it may be said in a general way that they will not develop sufficiently for many years to import much structural timber and their exports are solely of valuable woods which are not important in this discussion.

BRITISH INDIA.

The exports of India consist of teak and other valuable woods, and it is found necessary to import structural timber. Thus India, while an export country from the point of view of value, is an import country if only common woods be considered, and will no doubt so continue, for any greater supply made available by better transportation facilities will be offset by greater consumption, following development of industries. The following table gives the exports of India for 1903-4, and shows the kind of forest products exported.

Exports of India, 1903-4.[a]

Material.	Quantity.	Value.
	Tons.	
Caoutchouc	90	$115,732
Lac	11,781	9,079,320
Sandal, ebony, and other ornamental woods		403,163
Cutch and gambier	5,652	657,904
Myrobolans	61,480	1,403,429
Teak timber	73,913	3,048,536
Cardamoms	128	112,538
Total		4,820,622

[a] Schlich, Forest Policy.

JAPAN.

Conflicting figures are given by different statisticians on the timber trade of Japan, according to how much they include under timber. If only structural timber is considered, Japan is an importing country by a small margin, while if all woods be considered it is an exporting country. Japan can supply home needs when all the forests are accessible, but will probably not be able to export any saw-log timber. Certainly this country can not look for any supplies from Japan, for any surplus will in all probability go to Manchuria, since the shorter distance and Japan's interest in developing that country would enable it to outbid the United States. The following table gives the exports and imports of wood and wood products, except match wood, in recent years.

Value of exports and imports of Japan.

	1892.	1896.	1900.	1901.	1902.	1903.	1904.
Export	$135,000	$460,000	$980,000	$655,000	$660,000	$980,000	$1,335,00
Import	40,000	145,000	450,000	355,000	380,000	335,000	255,00
Net exports	95,000	315,000	530,000	300,000	280,000	645,000	1,080,00

[a] Endres, loc. cit.

SUMMARY FOR ASIA.

A brief summary of Asia results in the following conclusions: (1) China and Australasia are import countries; the imports of the former will increase rapidly, while Australasia will probably not increase the amount of her import much; (2) Japan and India export valuable woods and import structural timber; (3) these countries will be buyers of saw-log timber, and can not be counted on as possible sources of supply for the United States, but must be regarded rather as possible competitors; (4) the Philippines, though now an importing country, should be able to export sufficient timber, when the wood industry is developed, to offset the imports.

AUSTRALASIA.

There is a difference of opinion as to whether poor condition resulting from abuse or inaccessibility is the cause of the insufficiency of Australasia's forests to supply home needs at present. In any case, the imports are sure to continue to increase for some years, and it is very unlikely that any surplus timber for export will ever be produced. The following table gives the net exports or imports of each of the colonies for the period 1894–1899:

Value of net exports and imports by colonies.

	Net exports.		Net imports.
Western Australia	$789,500	Victoria	$1,364,000
New Zealand	758,500	New South Wales	1,344,000
Tasmania	154,500	South Australia	1,003,500
Queensland	29,000		
Total	1,731,500	Total	3,711,500
		Total net exports	1,731,500
Net imports of all Australasia			1,980,000

From A. A. Radzig, loc. cit.

HAWAII.

Hawaii, with only about 1,175,000 acres of forest, and developing industries, can export only a trifling amount of timber.

THE PHILIPPINES.

The Philippine Islands contain about 49,000,000 acres of wooded land, and the estimate per acre given is 2,500 board feet, which gives a total of 122,500,000,000 board feet of merchantable timber. The Philippines import timber for two reasons—the inaccessibility of their own forests at present, and the need of light, easily worked wood. In time, as transportation is developed and the forests are made accessible, the native forests should supply nearly all the home consumption, and leave enough over for export to equal or surpass the quantity imported of certain classes of timber which are not found in the islands. But owing to the small amount of total stand, and the fact that there are only about 2 acres per capita in commercial forest, the increase in consumption with development of industries and increase in population will prevent the timber export from ever being an important factor in supplying the United States.

TROPICAL AND SOUTH AMERICA.

MEXICO, WEST INDIES, AND CENTRAL AMERICA.

These States now import timber not so much because they have none, but for the reason that it is at present inaccessible. Whether forest exploitation will develop as rapidly as other industries and the amount of imports remain stationary or be reduced or whether they will increase can not be safely predicted. It would seem that there will always be an export of mahogany, cedar, and other valuable woods, and it is most probable that there will continue to be an import of common woods.

SOUTH AMERICA.

For many years South America will continue to export hard woods, dyewoods, etc., and import lumber and construction material. Eventually, as the countries develop, the great forests now inaccessible will be opened up, and should supply home consumption, which will have increased greatly by that time. The imports will no doubt not increase to any serious extent, but are more likely to diminish. At the same time, the exports can not be counted on as a source of supply for this country for the reason above stated—that by the time the forests are accessible the country will have developed so much that home consumption will have greatly increased, and also because the forests are so situated that logging and transportation will be so costly as to prohibit the use of the wood for construction in this country.

NORTH AMERICA.

ALASKA.

Alaska has approximately 107,000,000 acres of forest land, of which 37,000,000 acres, situated along the south coast and the river valleys, bear relatively heavy forests of valuable species, while the remaining 70,000,000 occupy the interior to the limit of tree growth. The interior forest consists for the most part of scattered stands, and only from 50 to 75 per cent of it can be said to be actually forested. Estimating these stands to run 500 board feet to the acre, the interior forest contains not over 21,000,000,000 feet, board measure. This timber runs small and knotty, and is insufficient to supply the needs of the mining population, largely because much of it is inaccessible with the present means of transportation. With the increasing development of mines it is safe to assume that this interior forest will continue to be needed for local consumption and may fall short of supplying it. The forests of the south coast and of the river valleys, on the other hand, are often dense and the trees large. Toward the north the trees fall off in size and the forest gradually assumes the character of the northern forest. Estimating the average stand per acre at 2,000 feet, the total stand for this forest amounts to 75,000,000,000 feet, board measure, not quite twice the annual lumber cut of the United States. In this part of Alaska fisheries and oil developing are the principal industries, so that the home consumption of timber is not so great, and in all probability this region may in the future, when transportation is developed, be able to export timber to the United States. However, owing to the relatively small amount of forest, it can contribute but a very small part of the timber used by this country.

CANADA.

The Canadian forests are being cut and burned faster than they are growing, as shown in the first part of this article, and yet the exports are growing steadily, as shown below:

Yearly average and values of exports of Canada.[a]

1881–1890	$23,000,000
1891–1895	23,450,000
1896–1900	27,825,000
1901	29,850,000
1902	33,500,000
1903	31,400,000

In 1904 the value of wood imported was $9,000,000.

It is evident, then, that Canada, the only country which the United States can now count on for any considerable amount of timber, will not long remain a source of supply to the United States.

CONCLUSION.

The review of the timber trade of the various countries of the world shows a steady increase in wood consumption and imports of nearly all the leading import countries, and but three important countries, Russia, Finland, and Sweden, which can increase their export without lessening their forest capital. This increase will be needed in western Europe to make up the growing deficit there, and will not be a source of supply for the United States. Thus the tendency is toward a greater overcutting of timber on the part of the export countries, to make up the increasing deficit of the import countries, which policy, if continued, would lead to a universal shortage, with no surplus to draw upon. This picture, gloomy as it may seem, is offset by the birth of a new economic force—the general appreciation of the value of forests and the movement toward the introduction of rational forest management by all civilized peoples. There is no doubt whatever that there is enough accessible actual and potential forest land in civilized countries to produce, under proper management, an abundance of timber to supply indefinitely the world's growing demand.

Doctor Schlich states, in his Forest Policy, that by planting up waste lands in Great Britain, much of the annual import could be replaced by home-grown timber. If any material results can be expected in Great Britain, this country, with its great existing forests and large amount of permanent forest land, can certainly supply its timber needs. Not only of necessity, in view of the lack of any adequate foreign source of supply, but also from national pride and the desire to preserve a tremendous native industry, the United States should introduce rational forest management. At present, forest management would consist in large part of conservative treatment of existing forests with a relatively small amount of planting. If postponed until a timber shortage forces the United States to action, we should face the problem of the slow conversion of scrubby woodland into productive forest and the costly planting of denuded wastes on a very large scale. While the present area of wooded land in the United States is usually estimated as 545,000,000 acres, some of this is of no commercial value, and much is inevitably destined, with the increase in the population of the country, to be cleared for agriculture. The area of land so situated as to be permanent forest land is about 450,000,000 acres, of which 100,000,000 will consist of farm wood lots. The inevitable increase in wood consumption, following increase in population and growth of industries, will thus have to be supplied from a diminished forest area. Therefore the only solution of the problem of a wood supply is to begin now to prepare ourselves for making a diminished forest area supply an increased population. This means that the land should be surveyed and classified by the Government, and forest management applied to the permanent forest land now—before it is too late.

COST OF FORESTRY IN DIFFERENT COUNTRIES.

By H. S. Graves,
Yale Forest School.

A comparison of the expenses of forestry in different countries is necessarily unsatisfactory, because the forests differ in character and there is a very wide difference in economic conditions. In Europe systematic forest management was introduced many years ago. The forests are thoroughly organized, and the expenses of administration represent their maintenance, protection, and operation. In this country the work of forest organization has only just been started. Even our National Forests have only been roughly explored, and we have only estimates of the standing timber growing in them and its value. There are almost no roads, only a few satisfactory maps, insufficient demarcation of boundaries, very few fire lines, and the work of construction of headquarters, ranger cabins, telephone lines, etc., remains as yet to be carried out. Almost no working plans have been made for our National Forests, and the life history of the trees must be more completely studied before satisfactory methods of silviculture can be devised. Practically all of the work of organization of the forests remains to be done.

Other conditions enter in also to affect a comparison of expenses. In America and India there is great danger from fire, and large sums of money must be spent on providing adequate fire protection. In Europe, on the other hand, the danger from fire is very small in most places, largely because of a dense population, an enlightened public sentiment, and an organization of the forests which is the result of many years' work.

Again, the market conditions affect the kind of forestry which can be practiced. With constant good markets, as in Europe, it pays to use more intensive methods of forestry than where only certain classes of timber can be sold. For this reason the Germans can afford to spend on cultural operations proportionally larger sums than the Americans. In the same way the total expenses of forestry in a country are influenced by the methods of timber sales. If timber is sold on the stump the outlay is less than if the government does its own logging. The last system involves a large annual expense for logging which does not appear in the budget of a country which sells its timber standing.

These facts must be borne in mind in the study of the forest budgets of Germany, France, India, and the United States, which are discussed in the following pages.

A comparison of expenses in these different countries shows some astonishing differences. Prussia, with its forest of a little over 7,000,000 acres, spends each year about $14,000,000; India, with about 65,000,000 acres (including only reserved and protected forests), spends only about $4,000,000. The United States, with about 168,000,000 acres of national forests, spends only about $3,400,000. If these data are expressed in terms of the amount per acre, it is seen that the expenditure by Prussia is over $1.90 per acre as against that of the United States of about 2 cents per acre. In this connection it must be borne in mind, however, that Prussia did not expend so large a sum on forestry at the beginning of its work of organization. With the development of forestry and the increased demand for timber and the resulting high prices, it has been profitable to use more and more intensive methods and invest greater sums each year in forest cultivation. This is well illustrated in Prussia, which in 1849 spent for regularly recurring expenses about $2,000,000 each year, compared with $12,500,000 at the present time.

In other words, the expense of administration increases with the development of forestry. This is possible only when there are increased returns as a result of the increased initial expenses. This principle is illustrated in Prussia, where the net income has increased from less than $7,000,000 in 1848 to about $14,000,000 at the present time.

To carry out further the comparison of expenditures in the different countries, Prussia spends for salaries, including both administrative and executive forces, 52 cents per acre; France, 38 cents; India, a little over 2 cents; and the United States, a trifle over 1 cent. The average area in charge of a supervising forester in Prussia is about 10,000 acres; in the United States it is over 1,000,000 acres. While our western forests will not require a division into so large a number of administrative units as those of Prussia, the contrast is nevertheless exceedingly instructive.

Although the Prussian forests are already thoroughly organized, nevertheless the work of constructing and extending roads and bridges, dams, etc., is being pushed each year with an expense of over $500,000, and that is about the sum which is now being expended on all kinds of construction work in our national forests. In other words, for construction work, including buildings, telephone lines, etc., Prussia spends about 16 cents per acre and the United States about 3.5 mills. In reality the comparison ought to be reversed, for construction work constitutes an exceedingly important part of the first organization of a forest.

The great yield of timber and large returns in money from the European forests are the result of careful, intelligent forestry. Not only are the forests protected, but they are constantly improved; they are properly thinned to obtain the best possible conditions of growth, and open areas are planted with trees when reproduction can not be secured naturally. All of this involves expenditure of money. Such improvement work costs in Prussia $1,700,000 each year, or 23 cents per acre. Even in India there is an expenditure of over $173,000 a year for cultural operations. The expenditure in the United States is only about $50,000 for this item, a sum so small that it can hardly be expressed in terms of expense per acre.

One of the great problems in the United States is the training of men to handle the work of the national forests. At the present time the number of trained men available for the administration of the forests is entirely inadequate. The country is fortunate in having private schools which are educating men for federal service. The United States Forest Service is aiding these schools to a small extent, but the total amount expended is probably not over $1,000. This may be compared with $50,000 spent in Prussia, $37,000 in France, and $26,000 in India.

It is obvious from this brief comparison of expenses in different countries that the amount of money spent on the administration of the National Forests in this country is exceeding small, and it is perfectly obvious to anyone who knows the conditions that a very much larger amount is required to accomplish the purpose of the people of the United States in managing their government forests.

Expenditures for forestry in Prussia, France, India, and the United States.

PRUSSIA.

[From the budget of 1908.]

	Amount.	Per acre.
Recurring expenses:		
Superior staff	$1,433,590.00	$0.19

EXTENT TO WHICH FOREIGN METHODS OF FOREST ADMINISTRATION ARE SUITED TO CONDITIONS IN THE UNITED STATES.

By S. T. Dana,
United States Forest Service.

INTRODUCTION.

In the United States the science of forestry is still in the formative stage. Knowledge of the characteristics and requirements of the many species of trees composing the forests is limited; the total amount and distribution of forest wealth is not accurately known; and methods of administration are not as yet settled, but are subject to frequent change. In Europe, on the contrary, forestry as practiced to-day is the result of centuries of gradual evolution, and is consequently thoroughly systematized and its methods firmly established. While conditions in the United States differ materially in many respects from those in foreign countries, many of the general principles of forest administration are nevertheless of universal application, and the long experience of those countries in developing systems satisfactory to them may be of much value in establishing methods suited to conditions in the United States.

GERMANY.

Germany is generally acknowledged to have attained the greatest development in the practice of forestry, and is held up as a model of what may be accomplished by scientific management of the forests. There is scarcely a policy or a practice that has not been tried in that country, so that a knowledge of what has been found to yield the best results, and has been adopted as the permanent policy of the Empire, is of particular interest.

As in all other countries during the early stages of their development, the forests were at first neglected and abused. Not until the fear of a timber famine began to be felt was any effort made to protect or perpetuate them. As early as the fourteenth century, however, the supply of wood in certain localities had become so depleted that alarm for the future prompted the first attempts at forest protection. The earliest record of commercial planting is for 1368, when the city of Nuremberg successfully sowed several hundred acres to pine, spruce, and fir. These early attempts at forestry were local, however, and it was not until after 1500 that there was any systematic and general development of forest methods.

Following the close of the Middle Ages came a period of industrial development which, together with further settlement of the country, hastened the progress of forest destruction. With the danger of a general scarcity of timber confronting them the people were forced to devise some means of preventing waste and of securing a second crop. A beginning was accordingly made in all of the various branches of forestry, but it was not until within the last fifty to one hundred years that a settled policy of management became fully established.

It is interesting to note that in Germany the development of forestry was originally due almost entirely to fear of a timber famine and to the recognized necessity of taking immediate steps to maintain the wood supply. The necessity of preserving forests about the headwaters of streams in order to prevent and control floods and erosion was not one of the first causes leading to the forestry agitation, but this necessity is now clearly recognized, and protection forests are maintained at high altitudes throughout the mountainous districts, in which cutting is either wholly forbidden or is carefully restricted. This early neglect of the protective value of a forest cover was due largely to the fact that the greater part of Germany (75 per cent) is either level or hilly in character, and that the remaining mountainous portion was not heavily cut at first.

In Germany the fundamental principle of forestry, that the annual cut should equal the annual growth, has been clearly recognized. Accordingly, no attempt has been made to withhold the forest from use, but rather to regulate its use and to increase the amount available for cutting by increasing the annual growth through various cultural methods. This policy has been remarkably successful, as is evidenced by the fact that the annual growth for the Empire as a whole reaches the high average of 48.7 cubic feet per acre. This is in striking contrast to the United States, where the annual growth is estimated at about 12 cubic feet per acre. The excellent results obtained in Germany are due to the very intensive systems of management in use. These are made possible by the economic and industrial condition of the country. While 25.9 per cent of the total land area is covered with forest, this is well distributed and is everywhere broken by patches of cultivated land and by settlements. The forest area per inhabitant is only 0.61 acre as against more than 6 acres per inhabitant in the United States. The entire forest is therefore more or less readily accessible and open to utilization. Good roads exist throughout the forest and greatly facilitate transportation.

In money returns the German forests are still more strikingly in advance of the United States than in wood returns. In the state forests of Prussia in 1902 the gross receipts amounted to $3.20 and the net receipts to $1.66 per acre. Yet Prussia, although the largest, shows smaller returns than any other of the important States in the Empire. Wurttemberg, for example, in 1901 received from its state forests gross receipts amounting to $8.25 and net receipts amounting to $5.41 per acre. This is in contrast to the gross returns of $0.011 and the net returns of $0.005 per acre received from the National Forests in the United States in 1907–8. These much larger returns are made possible not only by the more intensive systems of management in Germany, but also by the excellent market conditions and high prices for wood. The demand for all forest products is so strong and so uniform that stump and fagot wood and even leaf litter can, in nearly all cases, be readily marketed. Waste is accordingly so far reduced that practically the whole tree is utilized, as against only 50 per cent or less in the United States. Wood prices are uniformly from three to five times higher in Germany, and there is often a still greater discrepancy between stumpage prices in the two countries. This, of course, greatly increases returns, and it is a well-known fact that where the highest prices prevail the practice of forestry has also reached its highest development.

The returns per acre from the forest bear a fairly uniform ratio to the amount spent on it, which is very interesting and worthy of note. Greater expenditures are in nearly every case followed by greater returns. Prussia, for example, spends less on its forests than any other of the larger German States and also receives smaller returns. In 1880 it spent $1.09 per acre on its state forests and received a net return of $0.92; in 1902 an expenditure of $1.54 brought a net return of $1.66. Baden in 1880 spent $2.17 and received a net return of $2.38 per acre; while in 1902 it spent $3.89 and received a net return of $5.08. In general the net returns per acre pretty closely approximate the expenditures, so that any increase in the amount expended on the forest means a corresponding increase in the receipts.

In developing the different systems of forest management, the Germans have been particularly favored in that the forest is comparatively simple in composition, with only a few species of great importance. This simplicity in composition, which has been still further increased by the methods of management employed, is in marked contrast to conditions in the United States, where there are a great many species of commercial value, and a very irregular and complex forest. This difference in the character of the forests makes the German methods of management, as a rule, inapplicable in the United States without modification. The general principles involved are, however, frequently of universal application and have already been successfully used in the United States; and the German experience is also of value in pointing out errors to be avoided.

The Germans have found conifers to be a more valuable crop and to produce a larger yield than hard woods. They were fortunate in having the conifers largely predominant in the original forest, and the tendency has been to increase their representation, until now the conifers form 65½ per cent of the total forest area and the hard woods only 34½ per cent. Forests grown from seed have also been found to be more profitable than sprout forests, and have consequently been encouraged. In the management of the forests in the United States these facts have not been generally recognized; coniferous forests have been cut over and abandoned to an inferior growth of hard woods, while hard wood stands have been allowed to exhaust themselves by repeated sprouting, with no attempt to secure seedling reproduction.

The intensive forestry practiced in Germany to-day is, of course, the result of a gradual development through many years of experiment, accompanied by frequent changes in methods and opinions. For a long time the methods used were entirely of empiric origin, and as always happens in such cases the development of satisfactory methods was consequently slow. In 1870, however, the need of thorough and systematic experiments as a basis for technical work was officially recognized, and a forest experiment station was established in Baden in connection with the Polytechnikum at Karlsruhe. Other States followed this example, and the policy has met with much favor and has been largely instrumental in the development of a more satisfactory forest practice than was possible before. This increased efficiency in technical work, as a result of the establishment of forest experiment stations, is of particular interest to the United States, where this method of carrying on investigative work has just been adopted.

In regard to the part taken by the State in forest management in Germany two facts of particular interest stand out prominently: (1) The State exercises at least a controlling interest in the majority of the forests, and (2) the forests under state ownership uniformly yield considerably larger returns than those under private or communal ownership.

In Germany the Empire, or central Government, takes no part whatever in the management of forests, which is left entirely to the individual States composing the Empire. These, however, do not correspond at all closely to the States of the United States of America, but are rather independent countries which are simply banded together for political purposes. State ownership in these States, therefore, corresponds quite closely to federal ownership in the United States. In Germany, as a whole, 31.9 per cent of the forests are under state ownership, while in the United States 26.1 per cent are under national and state ownership. In Germany, however, the State takes an important part in the management of both communal and private forests, and 66 per cent of the total forest area is actually under state control. The United States has no control over the 74 per cent under private ownership, so that there is a most decided contrast between the influence exercised by the Government in the management of the forests in the two countries.

The advantages of state ownership are clearly evident in the greater returns yielded under it. For Germany, as a whole, the state forests yield 58.5 cubic feet per acre, while the private forests yield only 39.8 cubic feet; communal forests are intermediate, with an annual yield of 53.1 cubic feet. This high yield is undoubtedly due to the strong influence which the state exercises in the management of the communal forests, all of which are subject in some degree to state supervision. This varies from merely restricting the clearing or selling of the forests to complete management of them by the state precisely as if they were state property. The stricter the supervision of the state the greater are the returns in almost every case.

Communal forests are a natural result of the development of property conditions in Germany and are a European institution which has no counterpart in this country. They are an important source of revenue to the community, sufficient in some cases not only to make taxation unnecessary, but even to yield a surplus to be divided among the citizens. Although circumstances have not led to the establishment of communal forests in the United States, there is apparently no good reason why they should not be established with equally satisfactory results.

In addition to exercising more or less control over the communal forests, the State retains the right to regulate the cutting of certain classes of private forests without regard to the wishes of the owners. For example, private forests can not be cut clear where they are considered necessary for the protection of watersheds or the prevention of torrents. This is in marked contrast to the treatment in the United

States, where the national and state governments have not in any way attempted to restrict private owners in the management of their forests. The recent decision of the supreme court of Maine, however, that the legislature has a constitutional right to pass laws regulating the cutting of timber on private land where the cutting is liable to be detrimental to the public welfare indicates that the very desirable oversight by the State of private management in cases of this sort may in time be secured also in the United States.

On one point the authority of the state in Germany is limited even in the management of its own forests. This is in the so-called "servitudes," or "rights of user," which custom has brought into existence and which give certain individuals the right to appropriate to their own use certain products of the forest, such as the fagot wood or litter. These in time became such a hindrance that in Bavaria in 1852 the establishment of new servitudes was positively forbidden. Other States had the same experience, and attempts were made to get rid of these servitudes, with such success that they have mostly been abolished or restricted so far as to be no longer impediments in forest management. The United States is fortunate in never having been burdened by such rights, and the experience of Germany is a warning against allowing them to develop.

In practically all of the German States the forest administration comes under either the department of agriculture or that of finance. The administrative machinery is more or less alike in all of the States, and Prussia, which is the largest, may be cited as representative. There the technical work of the forest service is divided into three distinct parts, under directing, inspecting, and executive officers. The work of direction lies with the central office, at the head of which is a technical man known as the "oberlandforstmeister," assisted by council of technical deputies, or "landforstmeister." This central office has entire charge of the forest policy of the administration, questions of personnel, approval of working plans, and direction of forest schools, and in all things pertaining to the forest service acts as a court of last resort. For purposes of practical administration the country is divided into several inspection districts, each under an "oberforstmeister," assisted by a number of "forstmeister." The power of these inspectors is not merely advisory, but they are virtually administrative officers in practical control of their particular districts. These districts are, however, still further subdivided into smaller districts, or working units, each under an executive officer known as an "oberforster," who is in charge of a number of "forster," on whom falls the actual administrative and executive work in the woods.

It is evident that this system is quite similar to the present organization of the Forest Service in the United States, where there is a central directing office with six separate administrative districts, all of which report to the central office. These districts are further subdivided into National Forests, which form the administrative units. The forest supervisor, therefore, corresponds to the German oberforster and the forest ranger to the forster.

While there is thus seen to be a striking similarity between the general systems of organization in the two countries, there is an equally striking difference between the sizes of the administrative units. In the United States the average size of a district under a supervisor is over 1,000,000 acres; in Prussia the average area under an oberforster is about 10,000 acres, and in the little Duchy of Saxe-Coburg it is only 2,000 acres. In the United States the average size of a district under a single ranger is over 100,000 acres; in Prussia the average size of the area under a forster is about 1,700 acres, while in the Grand Duchy of Baden it is only 750 acres. Evidently intensive forestry even approaching that of Germany will not be possible in the National Forests until the size of the working area is materially reduced. At present even adequate protection is impossible, and correct technical management of the forests still more so.

Another difference between the German and American systems of administration is the greater division of work in Germany. There the technical, constructive, fiscal, legal, and police work necessary in forest administration are usually kept distinct; in this country the technical, constructive, and police work not infrequently have to be done by the same men. The result is that all three lines of work more or less interfere with each other, with consequent loss of efficiency.

In the matter of technical forest education, the German Government exercises a more direct influence than does the United States Government. In Germany the technical forest schools are conducted directly by the State, while in the United States the forest schools are all connected with private or state institutions. The Federal Government has no direct control over any of them. It has recently, however, made arrangements for giving instruction to rangers in cooperation with private institutions, and to this extent is following the lead of Germany, where ranger schools are well established. The Germans insist on a more thorough technical training for all of their forest officers than is required here, and no one is put in charge of technical forest work who has not had a thorough technical training.

In the dissemination of popular information concerning forestry the United States compares favorably with Germany. All available information of value is published promptly in the form of readable circulars, and the Government assists in educational work by furnishing speakers, by lending lantern slides, and by outlining methods of instruction.

FRANCE.

While France has not yet succeeded in developing such intensive forest methods as Germany, it has nevertheless clearly recognized the necessity for conservation of its timber resources, and its experience in reforestation is of particular interest to this country. By the middle of the seventeenth century the progress of forest destruction had reached such a point that Louis XIV's great minister, Colbert, remarked, "France will perish for lack of woods." The forest ordinance of 1669, which was passed through his influence, was a great step toward forest regulation, and, with the exception of the years during the French revolution, continued in force until the passage, in 1827, of the Code Forestier, which, with certain revisions, is the law of the present day. It is thus seen that while France early recognized the necessity of preserving its forests, the development of a satisfactory forest policy was comparatively slow.

The growing scarcity of timber was the cause of the first steps toward forestry, although the necessity of preserving the forests for the protection of watersheds and the water supply had a much earlier and much stronger influence than in Germany. As early as the sixteenth century the local parliaments enacted decrees against clearing in the mountains, but during the revolutionary period these restrictions vanished, the mountains were stripped of their forest cover, and tremendous damage resulted. The first work of recovery was begun in 1843, but owing to political events did not progress very rapidly until 1860, when the passage of a special law charged the forest department with the mission of extinguishing the floods. In 1882 this act was amended, so as to place the entire cost of the work on the State. Out of the 1,462 brooks and mountain streams which are considered dangerous in the Alps, Pyrenees, and Cevennes, 163 had in 1893 been entirely controlled, and 654 had begun to be "cured." Among the former were 31, the control of which fifty years ago was considered by engineers to be impossible. This probably furnishes the best practical example of the disastrous effects which follow deforestation in the high mountains and of the possibility of controlling torrents by afforestation.

In France the total forest area covers only 18.2 per cent of the total land area, and the forest area per inhabitant is 0.61 acre, precisely the same as for Germany. Although the annual consumption is only 24.6 cubic feet per inhabitant the supply is insufficient, and France is, next to England and Germany, the largest wood-importing country in Europe. This deficiency in the timber supply has not led to overcutting, however, and France, like Germany, has clearly recognized the fundamental principle that the annual cut must not exceed the annual growth. This in France is 37.9 cubic feet per acre, which, although high in comparison with the growth in the United States, is rather low compared with that in Germany. This is due partly to the less intensive management practiced in France and partly to the composition and character of the forest. Of the total forest area only 20 per cent is stocked with conifers, while 80 per cent is stocked with hard-wood stands, many of which are of sprout origin. Efforts are now being made to better the forest by converting sprout stands into seedling stands and by increasing the percentage of conifers.

In the development of a silvicultural practice the French have made considerable advance, but have not attained the perfection reached in Germany. An unfortunate tendency has been to stick to one system of cutting, regardless of conditions, and to make arbitrary marking rules. The result has been to deprive the local forest officers of any spirit of initiative and to force the adoption of certain set methods regardless of their applicability. The methods used were wholly of empiric origin until the necessity of introducing experimental methods was recognized by the establishment in 1882 of a forest experiment station at Nancy.

The greatest advances in forestry made by the French have been in developing new ideas regarding thinnings and in the work of reforestation. During the last century over 2,500,000 acres have been reforested, mainly in the mountains and in the sand dunes, marshes, and limestone wastes. The sand dunes along the coast of France, chiefly in Gascony, were formerly covered with forests, but by the destruction of these were turned into barren wastes. As early as 1717 small attempts at reforestation were made, but work was not taken up on a large scale until the last century, since which time 275,000 acres of moving sand have been fixed by plantations of pine. East of the dunes stretch the Landes, an area containing 2,000,000 acres of shifting sands and marshes. From 1850 to 1892, 1,750,000 acres of these were drained and successfully planted to pine at a cost of from $4 to $5 per acre, and a recent estimate places the value of this territory at $100,000,000. Between the valleys of the Loire and the Cher lies the region of La Sologne, a sandy, poorly drained plain upon an impenetrable calcareous subsoil. This region was originally densely wooded, but by 1787, 1,250,000 acres had become absolutely abandoned as a result of deforestation. Over 200,000 acres of nonagricultural lands have now been reclaimed by plantations of Scotch and mountain pine. Lands which fifty years ago could hardly be sold for $4 per acre now bring an annual revenue of over $3. In the province of Champagne 200,000 acres of arid limestone wastes have been reforested, mainly with pine, and now yield a net revenue of $2 per acre. The successful attempts at reforestation and controlling the torrents in the mountains have already been mentioned.

The results obtained in France along these lines are of special interest to the United States, where there is also much waste and deforested land which will never be valuable except for forest purposes, and which requires planting to restore the forest cover. France has proved that even arid wastes can be successfully planted and made to yield a net revenue.

The money returns from French forests resemble the wood returns in being less than is the case in Germany. In 1902 the state forests of France yielded a gross revenue of $2.45 and a net revenue of $1.47 per acre. A striking fact in this connection is that the present yield is actually slightly less than it was forty or fifty years ago. This is probably due to the fact that the condition of the forests has not improved materially during that time, and particularly to the fact that the forests are now largely composed of broadleaf species which, since they are to a great extent in poor condition, yield an abnormally low percentage of saw timber. The yield is, nevertheless, in striking contrast to the net returns of $0.005 per acre in the United States, where the species are, as a rule, both more valuable and more rapid growing. This is due partly to the higher prices and better market conditions, but far more to the greater care bestowed upon the forest. The expenditures equal about one-half the gross receipts, and, as in Germany, both the gross and net receipts show a noticeable increase with increase of expenditures. Although the forest has been under administration for many years, nearly 25 per cent of the total expenditures is still devoted to permanent improvements. In the United States, on the other hand, permanent improvements, which are essential to the proper administration of the forests, receive less than 5 per cent of the total expenditures.

As in all European countries, the State takes an important part in the management of the forests. Only 12 per cent of the forests is under state ownership, but the State also exercises a controlling influence over all of the communal and many of the private forests. In general, the state and communal forests show better returns than those under private management. The State exercises an even greater control over the communal forests than in Germany. Private owners, however, are free to manage their forests as they please, except in the case of protection forests necessary to prevent erosion, to maintain the water supply, or prevent the drifting of sand in dunes along the coast, or for the benefit of the public health. In all of these cases the State reserves the right to prevent the clearing of the forest and to prescribe the system of cutting. The State encourages cooperation with private owners, and is ready to undertake the management of private forests when requested to do so by the owners.

Much trouble has been experienced in the management of the state forests by the existence of rights of user, similar to those in Germany. These proved to be such a hindrance that in 1827, on the passage of the Code Forestier, a systematic plan was made to extinguish them, and the work may now be considered practically complete.

The administration of the state forests is under the minister of agriculture as president of the forestry council, with the director-general as vice-president and technical head. The central office also comprises three administrateurs verificateurs généraux, as chiefs of the three bureaux into which the administration is divided, each with two chiefs of sections, inspectors, and the necessary office staff. For purposes of local administration the forest area is divided into 32 districts, each under the charge of a conservateur, who corresponds to the German oberforstmeister. These are again subdivided into a number of cheffries, or inspections, which are administrative units, under inspectors and assistant inspectors, corresponding to the oberforster in Germany and to the supervisor in the United States. The actual forest work is done by gardes généraux, with the assistance of gardes généraux stagiaires, corresponding to the German forster and to the American rangers. These officials comprise the superior service, which is kept very distinct from the inferior service, composed of underforesters (brigadiers), or guards, and other workmen, corresponding to enlisted men in the army. The system evidently corresponds quite closely to both the German and American systems of administration.

France has only one forest school where higher technical education can be obtained. This school was established by the State in 1825 at Nancy, and in spite of various unfortunate experiences, has continued to the present day. It is intended primarily for the training of state foresters, and only 12 students are allowed to graduate annually, although foreigners and others who are not seeking state employment may study there. At Barres the State maintains two lower grade schools, one of secondary and one of primary instruction, for the training of forest guards. The superior service is composed of technically trained men, although these officials are not as a rule so thoroughly educated as in Germany. The opportunities for forest education in the United States and the part taken by the Government in spreading general information concerning forestry to the public compare favorably with France.

SWITZERLAND.

Switzerland is of interest because it is a republic, somewhat similar in form to the United States; because it shows intensive forest management, with high returns; and because it has developed an efficient system for the protection of its mountain forests.

The forest area occupies 21.2 per cent of the total land area. The forests are very irregularly distributed in the different cantons, but are present everywhere in the high mountains. A striking fact concerning them is the great number which are under communal ownership. Sixty-six and nine-tenths per cent are owned by communes and corporations, 28.8 per cent by private individuals, and only 4.3 per cent by the cantons, or States; the Bund, or Federal Government, does not share in the ownership of any of the forests, although it does take an important part in their management.

The forests are separated into protection and nonprotection forests, the former being such as are located at headwaters of streams or furnish protection against snowslides, landslides, floods, or climatic damage. All protection forests, whether public or private, are under federal surveillance, and must be surveyed and their bounds permanently marked. Their management is so regulated as to secure a sustained yield according to working plans sanctioned by the Federal Government; fellings must be made under the direct supervision of a trained forester, and clearing the forests is prohibited except by permission of the Federal Government.

All communal forests are subject to general supervision by the cantons. In nonprotective private forests the owner is free to manage his property as he pleases, with certain restrictions. Clearing is prohibited except by permission of the cantonal government; felling areas must be reforested within three years, and existing pasture woods must be maintained. Wherever protective forest areas can be created by the reforestation of waste land, this may be ordered, and either the Federal or the cantonal government contributes toward the expense of the reforestation. The law encourages the cooperative forest management of small holdings, the Bund paying for the cost of effecting such cooperation; it also empowers the Bund or the canton to enforce such cooperative management in specially endangered localities, as at the headwaters of torrential streams. This system of cooperation has been very successful, and the general system of federal supervision has met with excellent results. Torrents have been checked and controlled, and excellent financial results have been obtained. Planting has been resorted to in order to extend the forest area, particularly in the mountains, and the forest area has actually been increased 10 per cent in the last fifteen years.

For Switzerland as a whole the annual growth reaches the high average of about 51 cubic feet per acre. This also equals the annual cut, since Switzerland, in common with France and Germany, cuts only the annual growth. As usual, the state forests show the highest yields. During the four years prior to 1893 the average cut of the state forests was over 64 cubic feet per acre, while that of the corporation forests was only 42 cubic feet.

The money returns vary widely, averaging for most of the cantonal and communal forests between $3 and $9 per acre. In 1903 the net receipts of the town forest of Winterthur reached $11.69 per acre. The Swiss forests are thus seen to yield exceptionally high returns, partly on account of good prices and ready markets and partly on account of highly developed silvicultural practices. From 1895 to 1899 the average stumpage price for both timber and firewood was 6.3 cents per cubic foot—about the same as in Prussia. In the low country, however, wood prices are higher than the average in Germany, and coniferous saw material brings prices of from 12 to 15 cents per cubic foot.

Silvicultural practices are well developed and nearly all of the forests are managed under working plans. The Federal Government in 1855 instituted a two-year course in connection with the Polytechnikum at Zurich for the education of the higher forest officials, and in 1884 the course was increased to three years. In connection with the school at Zurich is a central forest experiment station, with several substations, where thorough scientific investigations of practical problems are pursued, the results of which have proved of great value in forest management. The cantons also give short courses for the education of the lower-grade foresters.

Switzerland repeats the history of other countries in having done but little for the preservation of its forests until forced to do so by circumstances. The first working plan seems to have been made for the Sihlwald, the city forest of Zurich, in 1680–1697; and the Bernese cantonal forests were first surveyed and placed under management from 1725 to 1739, and were fully regulated by 1765. These first efforts at establishing a forest practice were not general, however, although by the beginning of the eighteenth century the growing scarcity and increasing value of forest products had called attention to the necessity of protective measures.

Fears of a timber famine had previously caused a number of cantons to attempt to prevent further decrease of the forest area, but not until the severe flood of 1830 emphasized the protective value of a forest cover were these ordinances strictly enforced and a general movement for the better begun. The increase in torrential floods hastened the movement, and resulted in the delegation to the Federal Government of power to regulate the use of the protective forests. Forestry in Switzerland, then, was at first a result of the growing scarcity of timber, but did not develop rapidly until the severe floods resulting from the destruction of protection forests in the mountains forced the necessity of their preservation on the people. Rapid strides have since been made, and Switzerland has succeeded in proving beyond question that forestry can be profitably conducted, and that the use of protection forests can be satisfactorily superintended so as to maintain their productive capacity without lessening their protective value.

AUSTRIA.

Austria is of particular interest because forest conditions more closely approximate those in the United States than do those in any other of the countries considered. Austria shows variable forest conditions in different parts of the country, with considerable areas of virgin forest in the mountains; private ownership is more extensive than elsewhere in Europe, and the state forests are only now being thoroughly organized.

The forest covers 32.5 per cent of the total land area, with 0.91 acre of forest land per inhabitant. This large forest area enables Austria to be one of the few wood-exporting countries of Europe. This export is largely at the expense of the forest capital, however, since the annual cut varies from 60 to 67 cubic feet per acre, while the annual growth is only 42.4 cubic feet. This high yield for a country which is relatively undeveloped as compared with Germany, France, and Switzerland, is due partly to the fact that the forest is composed mainly of conifers (82 per cent), and partly to the fact that rapid strides have been made toward conservative forest management within the last fifty years.

In the northwest provinces, such as Bohemia, Moravia, and Silesia, where the population was denser than elsewhere, and where the influence of Germany was most strongly felt, the forests were early taken care of and forest management well developed. German methods were largely followed, and in some places almost model forests were in existence as early as 1848. In the more inaccessible mountain districts, however, the forests were for a long time neglected, and it is only within the last fifty years that material progress has been made in bringing them under management.

The state forests comprise only 7.3 per cent of the total forest area, and lie mainly in the more remote mountain districts. Twenty-six per cent lies in the plains and foothills, 49 per cent at medium elevations in the mountains, and 25 per cent in the highest mountain region up to the limit of tree growth. This region is largely undeveloped and inaccessible, so that for twenty years from 1874 to 1893 the annual net returns amounted to only 26.8 cents per acre. This is in striking contrast to the high returns in the more thickly settled European countries to the north and west. It is also in equally striking contrast to the net returns of 0.5 cent from the National Forests in the United States, where conditions are somewhat similar to those in Austria. Working plans have been prepared for most of the state forests, and by 1898 nearly 82 per cent of them were under regulated management. The silvicultural systems employed are largely based on those in use in Germany. They are, however, less intensive, are better adapted to the sparsely populated mountain districts in which most of the state forests lie, and are therefore more applicable to conditions in the United States.

One of the most difficult problems which the State has had to solve is the reforestation of the "Karst," a dry limestone waste lying in the mountain and hill country of Istria, Trieste, Dalmatia, Montenegro, and adjacent territory skirting the Adriatic Sea. This area was originally well forested with conifers and hard woods, but through reckless cutting, burning, and pasturing was reduced to a barren waste. Attempts to reforest it have not been wholly successful, and much remains to be done. A small portion of it has been planted and a considerable area reforested by protective measures, particularly by the exclusion of goats. Enough has been done to prove that the waste can be restored to its original forested condition, although at the expense of much time and money.

The private and communal forests are not so well managed as those belonging to the State, but great improvement has been shown in their management in the last twenty-five years, and more and more of them are being brought under the regulation of approved working plans. According to the general rule in Europe, all protection forests, including those under private ownership, are under state supervision, and cutting in them is carefully restricted. No forest can be absolutely cleared away without permission, and private owners may be compelled to restock blanks in their forests if these have a protective value. A unique feature of the relation between the State and private owners lies in the so-called "forest protective service." The severe floods of 1851 called attention forcibly to the necessity of forest protection, and an organization was created to manage the state forests, supervise the management of corporation forests, and afford police protection to both. In 1883 the functions of this service were extended "to instruct and encourage forest owners in forest culture, and to manage forests so designated to be managed." This service has proved so satisfactory that owners have freely availed themselves of it, and now ask constantly for its extension. It has succeeded in bringing about extensive cooperation with private owners, and about 60 per cent of the Austrian forests are now managed under working plans.

The organization of the state forest administration is much as in Prussia. The forest service is in the department of agriculture, with an oberlandforstmeister at its head. The country is divided into a number of inspection districts in charge of oberforstmeister and forstmeister. These are further subdivided into working areas under oberforster, with the assistance of "forstwarte" as executive officers. The average size of a district under an oberforster is 452,762 acres, which corresponds more closely to the size of an area under a supervisor in this country, although still but half as large. There is a more marked contrast in the area under the management of a single local officer. The average size for this in Austria is 13,880 acres, as against more than 100,000 acres under a single ranger in the United States.

There are a number of forest schools in Austria for the training of both of the higher and the lower grades, and an excellent state school at Vienna. There are also a number of forest experiment stations in the country, which have done much for the advancement of forestry.

CONCLUSIONS.

This brief review of foreign methods of administration brings clearly to light certain facts which can well be used in developing methods of forest administration in this country, and which it may be well to summarize here.

The experience of foreign countries has invariably proved that evil results follow if the forest is neglected and recklessly exploited until its preservation and protection is made absolutely necessary by fear of an impending timber famine or by disastrous floods. Many years and great expense are required to restore the forest to its normal productive capacity, whereas this capacity might have been greatly increased at much less expense of time and money if steps had been taken early enough.

The Europeans have also proved not only that forestry is necessary if the forests are to yield the best results, but also that it is profitable. The more intensive the forestry practiced the greater, as a rule, are both the wood and the money returns. The more that is spent upon the forest per acre the greater are the net returns received from it. Economic conditions in this country at present do not permit in many places of as intensive methods as are possible in Europe. The principles involved are applicable at once, however. Measures for forest preservation should be taken before it is too late; waste should be reduced to a minimum, more money should be spent on the forest in order to increase net returns, and above all the annual cut should be limited to the annual growth in order not to deplete the forest capital.

Foreign silvicultural methods are not usually applicable without change, but the general systems have been adapted with success to conditions in this country, and should be still more widely used. The important point to be recognized in avoiding the mistakes made abroad is that hard and fast, arbitrary rules seldom yield good results, and that the system adopted must be elastic and adapted to specific conditions. France, in particular, has proved that barren wastes and denuded mountain slopes can be successfully reforested, and this system of reforestation is as applicable in this country as there. Wholly empiric methods of forest management have invariably failed to yield the best results, which can be obtained only by systems based on carefully conducted experiments and thorough research work. Forest experiment stations are, therefore, a necessity if forestry is to reach its highest development.

A striking point concerning forestry abroad is the important part taken by the State in the management of communal and private as well as of state forests, and the considerably greater returns obtained under state management. All communal forests are subject to some form of state supervision, and many of them are managed precisely as if they were state property. Private forests necessary for the protection of watersheds or the welfare of the general public are also subject to state control; they can not be cleared, cutting must be done as prescribed by the State, and all cuttings must be reforested. Other private forests not necessary for protective purposes can usually be managed as the owner desires, but cooperation with the State in the management of such forests is common, so that the State also exercises a large influence in the management of private forests. State management is the most stable and efficient, and almost invariably yields the best results. There is apparently no sufficient reason why this should not also be the case in the United States. Government supervision of protection forests, where necessary for the welfare of the public, can hardly be considered as unwarranted encroachment on private rights, and might well be adopted here. More extensive cooperation between private owners and the Government in the management of other private forests would also undoubtedly yield good results and should be encouraged as much as possible. Communal forests have arisen in Europe as a result of the economic development of the country, but they have given such excellent results there and have proved so profitable that it would seem as if similar town and city forests could be advantageously established in the United States.

In general the organization of the Forest Service for the administration of the National Forests in the United States is similar to that in most European countries. The most noticeable differences lie in the much greater area under the administration of a single executive officer in the United States and in the lack of technical training in many of the men engaged in technical work. The forests can never be properly protected nor cared for until the working areas are so reduced in size that a man can adequately care for his district, and until a thorough technical training is required of men engaged in technical forest work.

At present the results of forest administration in the United States do not compare favorably with those attained in Europe. This is largely due to economic conditions, which have made impossible the development of very intensive forest practices, and to the lack of public interest in forestry and failure to realize its necessity and practicability. There is no good reason why this should continue, and no reason why the United States should not secure in time fully as good results as are now obtained in Europe. Forestry in this country is still young and time is necessary for its development; but this development can be hastened and guided by using the experience of European countries and by adopting, so far as conditions warrant, those methods of administration which have proved successful there.

FOREST FIRES.

By Clyde Leavitt,
United States Forest Service.

SUMMARY.

Fire is the greatest enemy of the forest. The lack of reliable statistics is the greatest obstacle to the securing of effective measures for fire prevention and control.

DAMAGE FROM FOREST FIRES.

More than 2,000 people perished in forest fires in the United States in the nineteenth century. During the past thirty-seven years there has been an annual average of 50 deaths from this cause.

The value of the standing timber destroyed has varied from $25,000,000 to more than $100,000,000. The direct annual loss has averaged $50,000,000.

The destruction of the young growth, though never included in estimates of fire damage, is a principal item of loss. The natural restocking of burned-over lands takes place very slowly or not at all. Had fires been prevented on nonagricultural lands now unproductive because of forest fires, 32,000,000,000 feet of timber, valued at $64,000,000, would now be produced annually on this land. The amount of this loss is equivalent to 80 per cent of the total lumber cut of the United States, or 32 per cent of the total consumption of wood material of all kinds.

Not less than 20,000,000 acres of young growth are burned over annually. At $10 per acre, the cost to replant is $200,000,000. Repeated fires have totally destroyed the forest over immense areas of nonagricultural lands and rendered the restoration of forest conditions possible only by artificial planting at great expense. Even where the forest has not been destroyed, its composition over immense areas has been changed for the worse.

In mountainous regions, deterioration and erosion of the soil, due to forest fires, cause a loss that is in many cases greater than that resulting from the destruction of the stand of merchantable timber and of young growth.

The destruction of the forest by fire results directly in an impairment of the regularity of stream-flow, tending to cause an alternation of flood and drought. Thus are brought about great losses to irrigation, water power, navigation, and other interests.

Fires, by reducing the available supply of raw forest material, have increased the cost of all forms of forest products.

The forest, if properly protected, is a reproducible resource; to be treated as a crop, differing from ordinary farm crops only in the time element. Under present conditions, the forest is exhausted, like the mine. The lumber industry is nowhere on a permanent basis, but has moved steadily West or South. This is true also of the naval-stores industry.

The power of the community for development through taxation is decreased by forest fires, since taxable property of great value is destroyed. This in turn is reflected in a general lowering in the values of all remaining forms of property.

CAUSES OF FOREST FIRES.

The principal causes of forest fires in the West are railroad locomotives, campers, and lightning. In the East and Middle West the principal sources of danger are the clearing of land and sparks from railroad locomotives. In the South practically all the forest fires are set intentionally, the greater part of the forest area being burned over annually.

In general, the great majority of fires are due to carelessness and ignorance.

FIRE PREVENTION AND CONTROL.

Damage by forest fires is practically preventable. In the United States, however, the people as a whole have never realized that fire protection is sufficiently desirable to make it worth while, or that it is practicable as a sound business measure.

Preventive measures are (1) administrative; (2) legislative; (3) educative. The aim of the second and third is to secure adoption of the first.

Of administrative measures, the most effective are patrol, brush burning, fire lines, back firing, the construction of roads, trails, and telephone lines, and the use of lookout and observation towers. Of these the one most vitally essential is patrol.

Legislative measures have in general been inadequate on account of lack of enforcement. A strict enforcement of existing laws would go far toward removing ignorance and indifference.

The present tendency toward replacement of coal by the use of electricity or petroleum as motive power on railroads traversing forest lands offers the greatest encouragement for the future.

Educative measures are of primary importance, because it is through them that the adoption of administrative and legislative measures is secured. The most effective is the dissemination of information concerning the causes and effects of forest fires and the methods by which they may be prevented or controlled.

RESULTS ACCOMPLISHED BY THE FEDERAL GOVERNMENT.

The national forests, though undermanned, offer the best example in the United States of an efficient system of fire prevention and control. In 1904 the area burned over was 0.66 of 1 per cent of the total area of the forests, exclusive of Alaska and Porto Rico; in 1905, 0.31 per cent; in 1906, it was 0.094 per cent; and in 1907, 0.14

per cent. The value of merchantable timber destroyed in 1907 was only 40 per cent of that burned the preceding year. The merchantable forest burned over in 1907 represented but 0.02 of 1 per cent of the national forest area.

The Forest Service cooperates with States and counties and with private owners and railroad companies for better fire protection on the national forests and on areas adjacent, the burning over of which would be a menace to the forest property of the Government.

On military reservations and national parks damage by fire is reduced almost to a minimum on account of the presence of federal troops. On Indian reservations until very recently practically no steps have been taken to prevent the occurrence of fires or to control them after starting. As a result there has been immense loss. On the public domain no steps whatever are taken to prevent or control forest fires.

RESULTS ACCOMPLISHED BY STATE GOVERNMENTS.

The action taken by States has been altogether inadequate. The best results have been accomplished in New York, New Jersey, Pennsylvania, Wisconsin, and Minnesota. More state forests should be created, and protected and administered at state expense.

RESULTS ACCOMPLISHED BY PRIVATE OWNERS.

On probably not more than one per cent of the 450,000,000 acres of forest lands in private ownership in the United States is there a system of fire protection in which the object sought, and for the most part accomplished, is the prevention of fires rather than the mere control after the fires have actually begun.

INTRODUCTION.

Of all the enemies of the forest, fire has without exception been the most destructive and far-reaching in its effects. Forest fires have occurred since the earliest periods of which we can gain any record. That disastrous fires were started by natural causes in the earliest history of the country can not be questioned. That with the advent of man the damage has vastly increased is equally true. Without adequate protective measures there is no question that the risk from fire on forest land would continue to be greater, year after year, as the country is opened up by railroads, and clearings are made by settlers, and as timber is cut by the logger. All experience goes to prove that fire follows the railroad, the settler, and the lumberman. Occasionally large forest fires occur which assume the proportions of national disasters, and public sympathy is temporarily aroused for the immediate sufferers. Such a fire was the one which occurred during the first days of August, 1908, in the mountains south and southeast of Fernie, British Columbia. The death loss from this fire was 18 people and the value of timber and other property destroyed was more than $6,000,000, and 6,000 people were made homeless.

Fire had been reported as burning on cut-over lands near Fernie for some time previous to the disaster, but until a heavy wind sprang up and caused the rapid spread of the flames no attention was paid to it and no attempt made to extinguish it. According to the newspaper report, it was commonly supposed that "the fires were doing no damage." This state of mind is typical of what has long been the attitude of the great majority of the American public toward the fire problem. Some progress has been made toward overcoming this point of view, but the results, as expressed in concrete form, have been pitifully inadequate. The damage from forest fires in the United States amounts annually to many million dollars and occurs in many different forms. The greatest obstacle to securing the adoption of adequate measures for the prevention and control of forest fires has been the almost total lack of reliable statistics of fire loss. It can hardly be conceived that remedial measures could long be delayed were the people as a whole fully informed of the incalculable economic loss that is being sustained each year from this source, and of the beneficial results that could be obtained by the expenditure of comparatively small sums in protection. For only a very small percentage of the forest fires that have occurred, even in recent years, has any attempt at an estimate been made.

Outside of the loss of buildings and personal property, the only item ever taken into consideration in estimating fire loss has been the single one of standing merchantable timber. Other items, frequently of far greater importance, but more difficult to estimate, have been overlooked entirely. Since no attempt has ever been made to secure accurate information as to the loss of standing timber, the estimates have almost without exception been far under the actual facts. A good illustration of this is the loss resulting from the severe fires in the forests of the northern peninsula of Michigan in 1906. It was stated by the commissioner of one of the railroads that of 250,000 acres in a single district along his line there was not a square mile within which fire did not appear. Severe fires occurred at the same time in six or more counties, yet the state fire warden placed the total loss at only $100,000, notwithstanding the fact that the losses were largely in perishable hard woods—maples, birch, etc.—which decay so rapidly that a satisfactory exploitation of these fire-killed woods is almost impossible. A local estimate placed the loss at $250,000. If, however, it be considered that an average acre in that region bears a stand of 5,000 feet b. m., with a stumpage value of $5 per 1,000, it will be seen that in order to cover even the latter estimate only 10,000 acres, or less than half a township, need have been burned over. The actual stumpage loss to the State from forest fires during 1906 is estimated by Prof. Filibert Roth, state forest warden, as being not less than $5,000,000, and probably far in excess of even that figure. The difficulty of securing accurate data as to fire losses will be readily admitted, since without a careful examination neither the area burned over nor the amount of timber destroyed can be determined. The information is, however, of great public value. It can not be expected that it will ever be satisfactorily furnished by private individuals or corporations. It is exceedingly desirable, therefore, that action be taken by the state and federal governments to this end. It is suggested that an attempt be made by the National Conservation Commission to secure the adoption of measures which will result in the uniform collection throughout the United States of statistics of this kind.

The time is rapidly approaching when the adoption of adequate measures for the preservation and perpetuation of our forest resources will become economically imperative. At the present time, however, stumpage prices are for the most part low, and the general adoption of any complicated system of forest management can hardly be expected. The soil and climatic conditions in the United States are, however, generally favorable to forest growth, and if protection from fires can be secured nature alone will accomplish a very great deal.

(A) DAMAGE FROM FOREST FIRE.

The damage done by forest fires may be classified under the following heads:

1. Loss of life.
2. Destruction of merchantable standing timber.
3. Destruction of young growth.
4. Effect on the distribution and composition of the forest.
5. Deterioration of the soil.
6. Injury to stream flow.
7. Injury to general business interests.

(1) LOSS OF LIFE.

More than two thousand people perished in forest fires in the United States in the nineteenth century. There have been a few great historic fires which have attracted general attention and are well known for the wide territory they have covered and the thoroughness of the destruction.

The most memorable forest fires which have occured are those in Wisconsin in 1871, in Michigan in 1881, and in Minnesota in 1894.

Forest fires raged in the northeastern part of Wisconsin in the latter part of September and first part of October, 1871, particularly in the counties on both sides of Green Bay. Four hundred square miles of territory were entirely devastated. Of several villages wiped out of existence, the principal one was Peshtigo. Governor Fairchild in a proclamation stated that the loss of life in the devastated district was at least 1,000, and 3,000 people were left entirely destitute.

The theater of the great forest fire in Michigan September 5 and the following days, 1881, was in the broad peninsula between Lake Huron and Saginaw Bay in the southeastern part of the State. The fire ran over 48 townships, a belt of timber country 60 miles in length, north and south, by from 10 to 30 miles in width, and comprising 1,000,000 acres. The number of people who perished was 138.

The village of Phillips, Wis., was burned by a forest fire July 26, 1894. Thirteen lives were lost and very much timber and other property destroyed.

In September, 1894, occurred the terrible Hinckley fire (Minnesota), in which 9 towns were destroyed and more than 600 people perished. Over 2,000 people were left destitute, and $25,000,000 worth of property was destroyed.

In September, 1902, forest fires in Oregon and Washington cost 18 lives and resulted in the destruction of timber and other property valued at more than $12,000,000.

Conditions during the year 1908 have been worse with regard to forest fires than for many years past. In British Columbia in August occurred the Fernie fire, already mentioned, where 18 people lost their lives. On October 16, near Alpena, Mich., 17 people perished while trying to escape from the little town of Metz, Presque Isle County. The town had been surrounded by forest fires which were closing in from all sides. A relief train was sent in order that the citizens of the town might escape. Two miles south of Metz the engineer saw blazing piles of cedar ties on each side of the track which had caught fire from the adjacent forest. Opening wide the throttle, he tried to dash through at full speed. About half way through the blazing ties the rails had been loosened by the heat, and the 5 cars and locomotive ran on the road bed until they came to a stop. In a moment the locomotive and cars caught fire, with the result that 17 known deaths occurred and many were severely injured by burns. Many towns through the Middle West have been threatened with destruction during the past season and a not inconsiderable number have been wiped out entirely. The complete destruction of the town of Chisholm, Minn., in September is a good example of this. No complete statement of the total number of deaths is possible. In Michigan alone, during the fire season of 1908, not less than 35 people lost their lives as a direct result of forest fires.

(2) DESTRUCTION OF STANDING TIMBER.

Large fires, such as those above described, have been comparatively few in number and of infrequent occurrence. From the earliest times, however, small fires have every year destroyed standing timber to the value of many millions of dollars, and it is these which are principally responsible for the vast aggregate of our loss from this source. The story of these fires is written in every feature of the forest, in the character of the soil and its cover, in the composition of the forest, and in the individual trees themselves.

The destruction of standing timber may occur in any one of the three following ways:

(*a*) By the killing of the timber, usually through ground or surface fires. Until within comparatively recent times but little attempt has been made toward the utilization of fire-killed timber, especially in the Western States. The worst fires have occurred in the more inaccessible regions, mainly owing to the fact that in such regions men were not available to stop the fires before they had burned themselves out. Under these conditions the utilization of dead material is clearly impracticable. Areas once burned over and on which the timber has been killed are generally more subject to later damage by fire than areas on which the timber is living. As a result of fire many trees fall to the ground after a time and furnish fuel for later fires. In many cases the same area is burned over repeatedly, the later fires destroying all the remaining seed trees which at first escaped. The result is in general a dreary, blackened waste which can be made to produce revenue only by the expenditure of large sums in forest planting.

(*b*) Injury to the individual tree. Light surface fires are frequently regarded as harmless. This, however, is far from being true, for in addition to destroying the young growth, surface fires injure many trees to such an extent that complete recovery is impossible. Through the burning of the bark at the base of the tree the inner layer of growing tissue is exposed to the air and in many cases becomes infected with fungous diseases through the spores which are generally plentiful throughout forest regions. As a result rot or dote occurs, and the value of the tree is partially or wholly lost by the time it reaches maturity. Younger trees are greatly reduced in value through the destruction of the fiber by the fungus, rendering it necessary to cut high stumps or to "butt off" a portion of the first log. The damage is especially great in the case of thin-barked species, as lodgepole pine and the spruces and firs. Western yellow pine and other species having a thick bark are comparatively unaffected by surface fires.

One of the best examples of the injurious effects of repeated grass fires on individual trees is seen in the longleaf pine forest of the South, where turpentining operations are carried on. In a virgin unboxed pine forest the damage to the tree is very slight. Perfectly sound trees seem to suffer not at all. Those on which the bark has been broken by natural causes or by chipping, to see if the grain is straight enough for rails, are slightly injured by fire igniting and charring these exposed places. As soon, however, as the trees are boxed the danger increases. During the period of operations the trees are protected by the raked circle at the base. As soon as the orchard is abandoned the raked space becomes covered with litter, and fire is easily communicated to the box and excoriated surface. The exposed face is covered with resin and the box is usually well filled with gum, both substances being highly inflammable. When flame is communicated to a box the resulting fire is of no mean importance. Not only does the resinous surface burn, but the heat is so intense that the flames, fed by the melting resin, shoot up the side of a tree, often for 25 feet. The spectacular part does not last over ten to fifteen minutes, but the box and base of the tree often continue burning for hours. To see a box burn one would not believe that the tree could survive, especially as two boxes often burn out on one tree, but it seldom happens that a tree is killed outright. The bark is wonderfully resistant and does not ignite or conduct heat even under the fiercest flame. The bark stripped off along the edge of a recently burned box is cool on the inner side, except on the very edge next to the fire.

The damage comes not from one fire, but from repeated fires. Each year the burned box and face on a tree is charred a little deeper, until at last it is burned entirely through at the base or so weakened as to allow the tree to be easily toppled over by the wind. Even if the trees live and stand there is no opportunity for them to heal over the wound, while, in addition, the removal of the antiseptic covering of wax gives access to insects and spores of fungi.

Lumbering usually follows the "turning loose" of a turpentine orchard, so that the two combined make conditions even worse. The slash furnishes fuel for hotter fires, while the opening up of the forest results in more "blow downs."

The injury to individual trees depends upon the severity of the fire, and this in turn upon the amount of grass, humus, or débris upon the ground. Many cases occur in which the vitality of the tree is injuriously affected without killing it outright. In such cases the tree is rendered much more subject to attacks by insects, such as bark beetles, than would be the case had it retained its vigor. In vigorous trees the presence of insects generally does comparatively little damage, unless they are present in great numbers. Under ordinary circumstances the number of insects is kept down by the copious flow of pitch, by which many of them are drowned. When the vitality of the tree, however, is weakened through the occurrence of fire at its base, the flow of pitch is lessened, the power of the tree to resist its enemies is partially destroyed, and it becomes much more subject to insect infestation than would otherwise be the case. Western yellow pine (*Pinus ponderosa*) is particularly subject to injury by bark beetles, though injury of this kind is not limited to any genus or species. When the beetles become so numerous that their galleries practically or completely girdle the tree under the outer bark, the death of the tree follows. Trees affected in this way become centers of infestation, from which new swarms of beetles spread and bring about the similar destruction of other trees. Very large areas of timber in the Rocky Mountains and in the Black Hills have been destroyed in this way. Insect-infested timber is usually sold at a large reduction, in order to encourage immediate utilization, and thus prevent further infestation. Unless cut within two or three years the quality of the timber becomes seriously impaired by rot, but if cut immediately the quality is not affected. Many areas of infested timber can not, however, be lumbered, unless at a distinct loss, on account of inaccessibility. There is no question but that forest fires, by rendering trees more subject to insect infestation, have resulted in the absolute loss of vast quantities of timber and in the partial loss of additional large amounts. No estimate of this loss has ever been made or can be made with any degree of accuracy.

(*c*) The third way in which timber is destroyed is through the complete burning of the timber itself. The loss here is, of course, absolute.

The actual amount of stumpage destroyed by fire can, of course, never be known. That it is appallingly large is conceded by all, and it is no exaggeration to state that more timber has been destroyed by fire than by the ax since the settlement of this country. According to an estimate based on the census figures, over 700,000,000,000 feet b. m. have been cut for lumber between 1880 and 1906. Unquestionably the amount destroyed by fire has been much greater.

The census for 1880 gives the area burned over during that year by forest fires as over 10,250,000 acres, with a property loss of over $25,000,000. This estimate is a very conservative one, since all unreliable or contradictory returns were absolutely disregarded. The following is the detailed statement:

Table of forest fires occurring during the census year.

[Tenth Census of the United States, volume 9, 1880.]

States and Territories.	Areas burned.	Value of property destroyed.	States and Territories.	Areas burned.	Value of property destroyed.
	Acres.			*Acres.*	
United States	10,274,089	$25,462,250	Minnesota	250,805	$1,395,110

Massachusetts	13,899	102,262	Wisconsin	406,298	725,610
Michigan	238,271	985,985	Wyoming	83,780	3,256,000

From year to year there is, of course, great variation both as to area burned over and damage done by forest fires. Until within the last four years, however, very little really effective work was done toward checking or fighting forest fires. The best estimates indicate that the acreage burned over in the census year (1880) is a fair average for the period immediately succeeding it. As the area of commercial forest became reduced through lumbering operations and some protection was afforded timber in the West by the creation of forest reserves, the average area of mature forest burned over annually became gradually less. This reduction in area has, however, been much more than offset by the fact that since 1880 stumpage values have increased more than fivefold. It is safe to say that from 1880 to the present time the direct annual loss occasioned by the destruction of commercial timber by forest fires has been from $25,000,000 to $100,000,000, and in some cases greatly exceeding even the latter figure. The average loss from this source alone has been not less than $50,000,000.

In a few of the States of the East and Middle West the question of protection from damage by forest fires has been agitated for a long time. As a result, forest commissions have in some cases been appointed and steps taken to determine the amount of damage done, in order that the public might be fully awakened to the necessity for taking definite action to lessen or prevent further damage from this cause. The following statistics as to areas burned over and the value of property destroyed are taken from these official reports:

Area burned over and amount of damage done by forest fires in Maine.

[From state forest reports.]

Year.	Area burned.	Damage.
	Acres.	
1903	269,451	$95,243
1904	6,958	12,655
1905	20,316	63,623
1906	7,528	20,919
1907	4,633	11,050

Annual loss in Massachusetts from forest fires.

[From State Forester's Bulletin No. 5.]

Year.	Area burned.	Damage.
	Acres.	
1885	....	$82,254
1895	....	107,150
1899	6,906	58,073
1900	51,807	140,456
1901	6,125	20,559
1902	51,578	26,526
1903	11,587	35,513
1904	1,339	14,764
Average	21,557	60,662

Figures for 1905, 1906, and 1907 not obtainable.

Acreage burned over and damage done by forest fires in Minnesota.

[From annual reports of chief fire warden of Minnesota.]

Year.	Area burned over.	Damage.	Year.	Area burned over.	Damage.
	Acres.			*Acres.*	
1895	8,265	$3,125	1902	18,285	$3,820

1906	35,779	878.28
1907	54,278	1,995.26

It will be noted that the figures for the damage done since 1880 are almost universally less than those given in the census estimate, and in some cases the discrepancy is very great. It should, however, be borne in mind that the States have never taken such pains to secure a careful estimate as did the Census Bureau in 1880, and that the figures given in the state reports are for the most part based upon mere guesses, since in practically no case has money been available for adequate investigations as to the actual area burned over and an estimate by a timber cruiser of the damage done. In general, little or no account has been taken of fires in the more remote and unsettled regions. Neither has there been any pretense of estimating for the young or middle-aged growth, which in a few years would have had a distinct market value. The importance of this is greatly emphasized by the rapid rise in stumpage prices and by the fact that, owing to reckless methods of lumbering and the almost total lack of protection from fire, the area of virgin commercial forest remaining uninjured by fire has rapidly decreased. It must be admitted that while the estimates in the Tenth Census are unreliable, those contained in the state reports are for the most part much more so. As a matter of fact, it is practically certain that almost without exception the figures given represent but a fraction of the actual damage. The need for reliable statistics along this line can hardly be overestimated.

(3) DESTRUCTION OF THE YOUNG GROWTH.

This is by no means the least of the damage which results from forest fires. The perpetuation of the forest by wise use constitutes the distinguishing difference between forestry and old-time lumbering. The forest should be regarded not as a mine which is exhausted when the material is once removed, but as a reproducible resource, the quantity and quality of which may by protection and management be made better than the product of nature alone and unaided. The perpetuation of the forest, however, implies the protection of the reproduction, since it is only by the development of the young trees that the mature forest is produced.

A fire in destroying mature timber kills at the same time the young trees which, had they remained, would have constituted the future forest. The damage done by surface or grass fires is not, however, generally realized. The general effect of surface fires upon young growth is well illustrated by the results of the annually occurring grass fires upon the reproduction of longleaf pine in the Southern States. Seedlings of this species if not killed outright, are injured by the killing or burning of the buds, leaves, and bark, and by the heat which injures the cambium and roots. The extent to which seedlings are injured depends primarily on their size. Certain it is that all seedlings up to an age of one year are consumed by even a light grass fire; the second year perhaps an occasional one escapes, but during the first two or three years practically all are killed, if not consumed. After this age each annual fire works more or less injury until a diameter of 2 to 4 inches is reached. A mere grass fire does not seriously injure seedlings three-eighths of an inch and more in diameter. The leaves burn off to within 1 inch of their base, but if the bud is uninjured the trees continue their growth. The bracts around the bud are very inflammable and where burned death results, but the buds are well protected by the whorl of leaves below, and hence are seldom killed. When the leader is killed, a side shoot usually takes its place. The side shoots by their horizontal or oblique position suffer more than an upright stem.

Although grass fires destroy nothing of present commercial value, they do destroy property of which the prospective or expectant value is very great. The truth of this principle will be more easily recognized with regard to forest plantations than where the young growth is the product of the unaided forces of nature. Where time and money are expended in preparing land and in planting young trees, the reasonableness of a claim for reimbursement will be readily admitted in case the plantation is maliciously or carelessly destroyed. In Europe this principle is fully recognized, and actions for damages are based upon the so-called "expectancy value" of the stand. This amount is determined by discounting for present value the amount which the stand would have been worth had it lived to maturity, making due allowance for rate of interest, time of harvest, probable amount and value of product, and other factors. Forest growth is a crop of the soil, precisely like agricultural crops, the only difference being in the manner of originating, caring for, and determining the maturity or time of harvest. This being admitted for forest plantations, it must also be admitted for areas on which reproduction is natural as distinguished from artificial, but upon the care and protection of which the owner has expended time and money with the intention of harvesting the crop when mature.

The loss due to destruction by fire of young growth upon wild forest land of mixed-age classes is no less real, since had only the mature timber been removed or destroyed the remaining young growth would have produced a commercial forest of easily ascertainable value within a definite period of time.

As emphasizing the point of view taken abroad with regard to the expectancy value of young forest growth, the attitude with regard to the insurance of forest property is of interest.

In many European countries the supply of virgin timber has long been practically exhausted, and the people are dependent upon what can be grown commercially, aided by imports from less settled regions. Stumpage values are high, and the revenue-producing value of forest land is fully realized. Under these conditions, planting is in many cases resorted to rather than natural reproduction. This involves a large initial outlay and a continual expense for necessary care. Profits are certain if the crop reaches maturity, but there is always the possibility of loss from fire or other natural agency. As a result, there has been developed a well-defined system of insurance of forest properties. With stability in business conditions, rates of insurance are reasonable, and the growing of forest crops is thus put on a sound basis and is subject to no greater risks than any other legitimate business.

In the United States the insurance of forest properties from damage by fire has been taken up in only a small way. A beginning has, however, been made and at least one company is now engaged in this class of business. With an increase in the number and size of planting operations for commercial purposes, the necessity for this form of insurance will be more fully realized and it will become as common as it is now in some parts of Europe.

It has been customary in the past for Americans to consider forest land of value only for its actual stand of merchantable timber. Of late years, however, the value of absolute forest land is coming to be recognized on account of its ability to create value through the production of wood crops, just as farming land is valued because of its ability to produce agricultural crops. Ownership in the land should be regarded as an investment and the wood crop as interest. Where the reproduction is destroyed, it may be anywhere from a few years to several centuries before a natural regeneration can take place and the land be again restocked. In the meantime the land is practically idle and the investment is producing no return to the owner. This is as true where the owner is the federal or a state government as it is where the land is owned by a corporation or individual.

The loss of time involved in the natural restocking of a burned-over area varies greatly according to the size of the burn, the number, kind, and location of seed trees, and soil and climatic conditions. Very large clearings or burns can not be restocked from trees now standing on the border. It is usually a question of the progression of the forest on the clearing by successive generations of trees. The seed trees now standing distribute seed as far as the wind will carry it, and reproduction occurs in greater or less amount within that range. Near the seed trees the stand may be good; farther away the forest is more open, and on the edge there are merely outposts representing the seed borne to unusual distances by exceptional winds. As soon as these trees are large enough to bear seed, reproduction will occur in the openings about them, and there will be a further advance of the forest. This will continue until the entire area has been restocked. This process is exceedingly slow, compared with the results obtained by planting or by natural regeneration where young growth has been preserved and protected.

How much the loss by the destruction of young forest growth amounts to each year is difficult to conceive, even approximately. There are about 600,000,000 acres of woodland in the United States. It may be assumed that 200,000,000 acres of this area are in forest still uncut and not burned, leaving 400,000,000 acres of cut-over and burned-over land. This land varies greatly in productiveness, but it is safe to estimate that on the average it is capable of producing an annual growth of 20 cubic feet per acre. Protection from fire alone would have secured this result had preventive measures been taken from the beginning. Proper management would greatly increase it. Over very large areas, natural reproduction can not now be depended upon, owing to unfavorable soil conditions and the absence of seed trees. Thus a great expense for artificial reforestation will become necessary to repair the damage caused by long neglect. The producing capacity of the 400,000,000 acres with fire protection alone would thus be 8,000,000,000 cubic feet, equivalent to 40,000,000,000 feet b. m. per year. On account of the destruction of seed trees and of young growth by forest fires, it is estimated that not to exceed one-fifth of this amount is actually being produced on this area. This leaves a net loss to the country of 32,000,000,000 board feet per annum. At $2 per thousand stumpage this represents an annual loss to the country of $64,000,000. The annual loss thus directly due to the failure of the country to adopt measures for the prevention and control of forest fires is equivalent to 80 per cent of the total lumber cut of the United States, or to 32 per cent of the total consumption of wood materials of all kinds.

There is another point of view from which this loss may be estimated. It may be conservatively stated that 5,000,000 acres of land are burned over each year on which there is a stand of young growth which, if protected, would become a valuable stand of commercial timber. It costs on an average not less than $10 per acre to plant cut-over or burned-over lands. At this rate the annual loss to the country from the destruction of young growth alone is not less than $50,000,000. As a matter of fact, the actual direct loss from this source is much greater. The above figure makes no allowance for the fact that if the area is replanted, the forest will be but 3 or 4 years old, while that destroyed will usually average considerably older, varying from 1 to perhaps 50 years. The loss of interest on the investment represented by the value of the land during the time thus lost is an important consideration.

(4) EFFECT ON DISTRIBUTION AND COMPOSITION OF THE FOREST.

Forest fires affect not only the composition or make-up of the forest, but its distribution as well. Where repeated fires result in the total destruction of the forest cover, its replacement through natural means depends upon many conditions, and may not take place for hundreds or thousands of years, if at all. In general, the replacement of the forest on large areas of burned-over lands in the Rocky Mountain region is exceedingly slow, while in the coast region and in the eastern States it is much more rapid.

The change in the composition of the forest depends entirely upon the intensity of the fire. When great damage is inflicted upon the soil, its ability to produce spontaneously a crop of trees similar to the one destroyed is lost, and the subsequent forest is only produced if at all, through the restoration of fertility, following the slow growth and decay of many generations of less valuable plants. On the other hand, where the fire is light, burning merely slash resulting from old cuttings, and destroying the reproduction without doing any material injury to the soil, it is not many years before a new vegetation establishes itself and no real change is brought about in the composition of the forest.

The time required to seed a burned area with the valuable species destroyed depends entirely upon the severity and extent of the fire. The light-winged seeds of the conifers travel great distances, but a complete seeding of the ground can not be depended upon for a greater distance than one-quarter of a mile from the parent tree. Assuming that a conifer must be at least 30 years old before it can produce fertile seed, it would take at least thirty years to seed a burn over half a mile in diameter, at least sixty years to seed a burn 1 mile in diameter, etc.

The spruce forest of the Northeast consists chiefly of an uneven stand of spruce, balsam, birch, maple, yellow birch, white pine, etc. When burned over the ground becomes occupied by a temporary type of light-demanding species, such as fireweed, bird cherry, popple, soft maple, and birch. The last three species are good sprouters and grow from roots already well established. The popple often grows from underground stems or suckers, thus adding materially to the rapidity with which it comes in upon burned areas. As these light-demanding trees grow in height the confers, being quite tolerant, come in under the shade afforded by the former and establish themselves in the stand. Birch, popple, bird cherry, and soft maple grow very rapidly at first, but they are not at all persistent in their height growth, and are soon overtopped and killed by the slower-growing but more persistent conifer. With the death and disappearance of the above-named hard woods, the forest resumes its coniferous character.

In the white-pine region of New England and Pennsylvania the prominent type is a mixture of white pine, red, white, and black oak, chestnut, maple, ash, etc., the hard woods tending to occupy the better soils. When a severe fire occurs, destroying the vegetable matter in the soil and killing young growth and seed trees, freer seeding and less exacting species like gray birch and pitch pine, and such shrubs as scrub oak and laurel, take possession. Eventually, however, the area will revert to its original type, as in the case of the spruce forest.

Where the fires are less severe, killing only the young growth and not injuring the soil, the effect is usually to favor the free-sprouting hard woods, which occur naturally on the better soils. As this is a prominent type it then becomes difficult for the more valuable white pines to recover the ground which they have lost.

In the upland longleaf pine region of the South, after an area has been culled by lumbermen so that only a thin stand remains and the ground is burned so closely as to prevent pine reproduction, there often occurs a thick stand of jack, scarlet, post, and upland willow oaks. There is thus formed a two-storied forest, with these oaks as the under story. The large pines in such a forest are present in varying numbers, from 30 to 40 per acre to 3 or 4, or occasionally entirely wanting over limited areas. The tendency of such a condition is to reduce the number and severity of the fires. The oaks by their shade reduce the density of the grass cover and the number of low shrubs so that often there is not sufficient fuel to support a fire. The bunches of wire grass are widely separated, and as the fallen oak leaves do not carry fire unless there is much head, a running fire soon loses headway unless fanned by a strong wind. Land of this character presents one of the most hopeless and deplorable features of fire injury. It is not safe to say that this worthless oak would not spring up upon the cutting of longleaf pine, but it would not cover the ground so exclusively were it not for the fires which kill the longleaf pine seedlings, which would compete against it for possession of the ground. With fire as an ally the oaks have all the advantage. Another advantage is the frequent oak mast as compared to the rare production of longleaf pine seeds. Even if both seed the ground and the seedlings share alike for the first year or two, the inevitable fire will kill the pines outright, whereas the oak will be killed to the ground only to sprout anew the following year or often the same season. The sprouts grow with marvelous rapidity and soon get above the fire danger and shade out the few pines that perhaps escaped the first fire. Once in possession of the ground, the oaks give no further opportunity for pines to establish themselves. Except for the damage to the soil there can be no harm resulting from fire in oak scrub land. If the oaks are injured so much the better. Prevention of the fires which give the oaks first possession is the thing to be sought for.

The effect of the fires upon the loblolly pine land of eastern Maryland and Virginia is illustrated by great stretches of waste land covered with a thick tangle of huckleberry, laurel, green brier, etc., with a scattering of loblolly and other pines. The loblolly is a free seeder and would take possession again were it not for the recurrent fires.

In a shortleaf pine region fire results in great damage to the forest. The reproduction of pine is largely prevented and an undesirable growth of inferior hardwood sprouts results, as described for the longleaf region.

In the Rocky Mountain region the struggle of the trees is not so much against each other as against adverse climatic conditions. Of these the most important is the low annual precipitation. Fires in that region have resulted in the laying waste of vast areas. The fact that seed years of the native species may occur only at infrequent or irregular intervals intensifies the uncertainty of reforestation through natural means. This is especially true of Engelmann spruce in the Rockies. Unless favorable climatic conditions and a good seed year happen to occur at the same time the seeds fail to sprout or the seedlings fail to live and the establishment of a new stand is delayed indefinitely. Seed, moreover, is not always plentifully produced, because in this high altitude and peculiar location the meteorological conditions are anything but favorable to regular, abundant seed production, and when seed is produced a large portion of it becomes food for birds and other animals. Of a large area in the southern portion of the Pike National Forest, Colorado, burned over about 1850, less than 10 per cent is estimated to have become restocked through natural means.

Two trees, however, are well adapted to cope with fire, the aspen and the lodgepole pine. The former certainly and the latter in many cases may be regarded as temporary types preparing the way for more valuable species like Douglas fir, yellow pine, and Engelmann spruce.

The relation of lodgepole pine reproduction to fire is an especially interesting one. In the first place, the cones often do not open, but remain on the trees for many years; and in the second place it demands a mineral soil in order to germinate well. Since fire provides a mineral soil and opens the cones, the lodgepole pine is favored by it, and the tremendous areas of logpole forests in the Rockies are largely the result of fire. This is not always true, however, for if the fire should come before the stand has reached seed-bearing age complete destruction will result. The reversion of timber land to chaparral, through repeated fires which kill the reproduction and eventually the seed trees, is one of the serious problems in the commercial forests. The chaparral is able to endure these repeated fires, since it sprouts from the root. It has in this way obtained possession of enormous areas once densely forested. One of the best examples in northern California is seen around the base of Mount Shasta.

The unwritten history of the Southwest is phenomenal. The prehistoric aborigines must have exerted a marked influence upon the vegetation of the country. Their fires, and those of the historic races, unquestionably account for the open condition of the forests. The high pine forests were their hunting grounds, and the vast areas of foothills and plateaus, covered with oak and nut-bearing pines, their harvest fields. Here they lived in their summer homes, kindled their camp fires, and harvested crops of acorns, nutritious nuts, and in many instances cultivated vegetables and cereals.

Possibly no forests on the Pacific coast show so small a percentage of regrowth and so slight a tendency to reproduction as do the forests of the Mogollon Mountains, which extend through New Mexico and Arizona. This is due not entirely to the arid condition, as is popularly supposed, but to the continued occupancy of the country for centuries by prehistoric races, who merged into the Indian tribes occupying the country at the present time. All through Arizona the regrowth of pine forests dates somewhere during the past half century, and with a few exceptions nowhere antedates the early settlement of the country by our own race.

From Puget Sound to the Gulf of California these people rambled at will, but their abiding place was on the border land between the forests proper and the "Staked Plains" in the Southwest. The extensive ruins indicate that they inhabited the fringe, so to speak, of the forests which, like vineyards, were working their way down from the mountain tops into the desert plains. The most potent and powerful weapon in the hands of these aborigines was a firebrand. It was alike used to capture the deer, the elk, and the antelope, and also to rout or vanquish the enemy. It cleared their mountain trail and destroyed the cover in which their quarry took refuge.

In the North nature was quick to heal the ravages of fire, and the damage of forest growth was reduced to the minimum. In the dry and more arid regions nature recuperated slowly, and the relentless flames left an indelible mark. In Chaco Canyon, where a deep arroyo or wash has cut the depth of 30 feet through a sedimentary formation, distinct strata of earth, impregnated with charcoal, from 15 to 20 feet from the surface, may be traced over an area of many thousands of acres. Elsewhere the alluvial and silt deposits and forest trees have recorded the unmistakable evidence of numerous and extensive forest fires which have occurred at intervals during many centuries.

How far the occupancy of the prehistoric and historic tribes has retarded the progress of foresting it is impossible to say, but it must have been no small factor. These areas—that is, those most frequented by the cliff, caveta, and pueblo builders—were then and are now of great importance, because in the region inhabited by them the battle between vegetation and the unfriendly elements was and is now fiercest. These areas form the boundary between the forest and the desert. Vegetation is here dwarfed, but struggling to enlarge its domain. Were it not for the long Indian occupancy and the ravages of fire incident to their habitancy, vast territories now barren wastes might be covered with a forest growth, at least such as is indigenous to arid regions. Irrigation would have reclaimed many hundreds of acres now hopelessly barren.

In Arizona there are no young forests of any considerable extent antedating a period of forty years and almost all of the regrowth has sprung up during the last quarter of a century. A single exception may be noted in the White Mountains, which have been occupied for a couple of centuries by the Apache Indian. These forests show in certain localities all classes of regrowth and are in marked contrast to the mountain country occupied by the Navajo Indians in the northeastern portion of the Territory. The Navajos have possessed sheep and goats and followed pastoral pursuits for over two centuries. The forests occupied by them show practically no regrowth. The Apaches have followed the chase and war and have entrammeled themselves with nothing but war ponies. The forests within their domain, where they have not seen fit to apply the torch in accord with their well-grounded supersitition that forest fires cause rain, show a regrowth gradating into many past decades.

Fire, with or without the aid of lumbering, is directly responsible for the chaparral upon the western slopes and foothill regions of the mountains of California. Of three and a half million acres examined in the mountains of Butte, Plumas, Sierra, Nevada, Yuba, and Placer counties, in southern and central California, approximately 213,730 acres are under chaparral cover. If an artificial grouping were made it would throw the chaparral into two types of classes: (1) That which has evidently been in possession for a long period of time, and (2) That which has taken possession since lumbering and fire removed or thinned the forest growth. In one case natural causes, mainly fire, are responsible; in the other largely the result of man through lumbering. In both cases the chaparral covers the sites of former forests, the main difference being the time and rapidity of the transition.

The first-mentioned type is found mainly at the higher elevation, seldom below 4,000 feet. These high, brush-covered ridges show external evidence of having been timbered, examination revealing the presence of old stubs and charred logs among the densest chaparral, often entirely covered with soil; while the soil conditions are as good as in the adjoining timber. Each succeeding fire reduces these evidences of former timber growth, kills a few more trees along the disputed boundary, and extends the line of chaparral farther back into the forest. The principal reason for the rapid advance of the chaparral at the expense of the forest on the higher elevations is that fewer species and less fire-resisting ones occupy these upper slopes. The fir, especially until the polewood stage is passed, is very susceptible to fire. It is, however, one of the first species to work back into the chaparral, and in many places would regain possession if it were not for recurring fires.

The chaparral of the lower slopes is practically the same as the other, save that it has appeared more recently, and is the direct result of lumbering followed by successive fires which killed the reproduction and the thinned stand of culled timber. The result of the change in composition of the forest from commercial timber to chaparral is that the capacity of the land to produce revenue in the shape of a valuable crop is lost for an indefinite period. An additional point is that the chaparral is less valuable as a protection to the watershed than a forest cover since the latter produces better conditions of soil and humus and is more effective in preventing evaporation. The presence of the chaparral cover, however, renders planting operations so difficult and so expensive that reforestation with commercial species is in most cases impracticable as a business measure.

In hardwood forests, in general, the effect of fire is to reduce the percentage of seedling trees, and to increase the number of sprouts. As sprouts rarely produce first-class timber, the result is deterioration of the forest. Fire also favors the freer-sprouting, faster-growing species like the chestnut and the black oaks, and the less exacting species. Frequent killing back, however, reduces the vitality of the stools and often kills them entirely so that large areas become covered with such shrubs as laurel, rhododendron, huckleberry, etc.

The effect of fire in the sprout forests, because of the density of the stand and moderate height of the trees together with the crookedness and irregular forms of growth, is even more destructive than in seedling forests of similar species. In young stands the destruction is often complete while the dead, half-burned stems that remain standing add to the danger of a second fire.

Many of the so-called prairies are capable of bearing forests and possibly were originally timbered. This is not only true of the great prairie belts of the Middle States where the western line of forests has been pushed far to the east through the agency of fire, but is also true of the prairies found within forest regions, such as those occurring in southern Minnesota, Illinois, Tennessee, etc. In many of the interior prairies forest conditions are already becoming rapidly established since the prevalence of fires has been decreased.

(5) DETERIORATION OF THE SOIL.

It is impossible to estimate even approximately the loss caused by the deterioration of the soil due to forest fires. In mountainous regions there is no question that the loss from this source is frequently greater than from the destruction of the original stand of timber. The building up of the soil in mountain regions is a matter of evolution, resulting from the decomposition of rock in place and of the vegetable matter formed by many generations of lower plants, or by the washing down of these constituents from higher slopes. On many slopes the presence of any forest growth whatever is due to the accumulation through the ages of a mass of organic matter which held the mineral particles of rock as they were gradually disintegrated, preventing their being washed to the bottom of the slope. It may take hundreds or thousands of years for the soil on a slope to reach a sufficient depth to produce a stand of commercial timber. When the forest growth and other ground cover are destroyed by fire and the organic matter partially or totally burned, the bare, shallow, mineral soil is left to be blown away by violent winds and to be washed away by the rains. The capacity of the area thus denuded to produce a valuable crop is in this way delayed indefinitely, and at the same time immense damage may be done by the deposit of soil thus washed down upon valuable farm lands below. This has been notoriously the case in the Southern Appalachian Mountains.

Where the slopes are not sufficiently steep to facilitate the washing away of the soil, forest fires by destroying the humus may affect injuriously both the fertility and the physical condition of the soil. The loss in fertility is of the lesser importance since of the constituents necessary to tree growth, one-half, namely, carbon, is furnished by the air, and almost all of the other half is furnished by the water of the soil. In general the soil is increased in fertility by the presence of forest growth, while the opposite is true of agricultural crops. The damage to soil fertility on lands not suitable for agriculture may thus be overrated, so far as the mineral composition is concerned.

The fertility of the soil for the support of forest growth is, however, much more to be found in the physical condition than in its mineral composition. In the case of agricultural lands the physical conditions can be regulated by artificial means, as by plowing and cultivating. This, however, is impracticable to any extent with regard to forest lands. The surface cover has an important influence on the physical conditions of the soil, and its destruction by fire may be most detrimental. Changes in soil conditions primarily affect water supply and stream flow, and for that reason will be discussed under the next heading. For the purposes of this subdivision it need only be remembered that the amount of wood increment is in proportion to soil conditions, and that a deterioration of these is reflected in a reduced annual wood deposit as long as the unfavorable conditions last. There is thus a distinct loss due to the rate of growth having been damaged, and the amount of wood increment being correspondingly decreased as a result of forest fires.

(6) INJURY TO STREAM FLOW.

Investigations indicate that the presence or absence of forest cover has but little if any influence in increasing the rainfall and the annual run-off. There is no question, however, but that the forest does subserve an exceedingly important function in regulating the disposition of the precipitation after it reaches the ground. It shades the soil and breaks the force of the wind, thus lessening evaporation, both of soil moisture and of rainfall. The result is that a larger percentage of the precipitation passes into the streams, either directly as a part of the surface drainage, or indirectly through seepage, and thus becomes available for irrigation or other purposes. The effect of forest cover in retarding surface drainage is also well recognized. This is accomplished by the mechanical effect of the vegetation in retarding the flow of surface water and by its function as an absorbent, changing the rapid surface run-off, with its great possibilities for damage, to the slower process of seepage drainage, whereby the volume of stream flow is equalized and its occurrence distributed through longer periods of time.

Where the forest fires result in the partial or total destruction of the forest cover the nice balance of nature is destroyed and the above conditions are reversed. The result is that snows melt more rapidly in the spring of the year, the soil washes away, or its physical condition is so changed that its capacity to absorb and retain precipitation is damaged, and an alternation of floods and droughts occurs, in place of the former comparatively steady stream flow. The value of streams for irrigation, power, and navigation is greatly lessened on this account, since the volume may be greatly decreased, or the flow cease entirely during the dry season, when it is most needed. Greatly increased facilities for the storage of water become necessary in case the water is to be used for irrigation. This added expense is further increased by the additional damage done by the silting up of reservoirs at times of flood water.

Concrete examples are not wanting, which demonstrate the results bound to follow if present lumbering methods are not modified and protection from fire secured.

A point not often considered is the effect of forest fires in increasing the number and severity of snowslides and landslides. It is a well-known fact that in Europe not only torrents, but landslides and snowslides are induced and aggravated by the removal of the forest cover, and also that the formation of these slides has been prevented by reforesting the denuded mountain slopes. Timber at high altitudes affords the best protection against snowslides. The importance of the forest in this respect was recognized in the Alps centuries ago, and wherever "ban" forests were maintained, immunity from avalanches to the extent of the forest has been secured. An interesting account is given of the ban forest of Urseren, which was reserved by the community as early as 1397, and of the constant fight which was necessary against reckless advisers to keep it intact, until now the beneficial effect is fully recognized and reforestations have been begun under the protecting walls or other safety works wherever the danger of avalanches exists.

Yet even timber forest is not absolute protection against avalanches, since the place of incipient formation of the slide may lie above timber line. There is no question, however, that the interlacing of the roots of trees has a decided tendency to prevent movements of the soil, and the mechanical obstruction furnished by the trees themselves is an important factor in preventing the inception of snow and land slides and in checking them when once formed. Conversely, the destruction of the forest cover at high elevations through the agency of fire, while not necessarily an original cause, undoubtedly contributes to the evil effect.

Snowslides are frequent in the Rocky Mountain region, more especially among the higher Colorado ranges. Hardly a year passes without the report of serious loss of life and property from this source from the regions near Silverton, Ouray, Aspen, and Leadville. In a number of instances entire mining camps have been engulfed. Landslides are of less frequent occurrence, but they do nevertheless occur, and are of increasingly frequent occurrence with the settlement of the country and the consequent denudation of forest lands on the steeper slopes.

In addition to the loss of life and property, the occurrence of snowslides has a bearing upon streamflow. The mechanical effect of both snow and land slides in removing the soil covering from steep, rocky slopes and in preparing the way for further washing and gullying is well known. But little attention has, however, been paid to the effect of snowslides upon the distribution of streamflow throughout the year. The snow which falls at high elevations naturally melts less rapidly than that which is deposited upon the lower slopes. A snowslide results in the transfer of an immense volume of snow from a higher to a lower altitude. Under the new conditions the snow in general melts more rapidly than would have been the case had it remained on the higher slopes. In addition, it must escape chiefly as surface run-off, instead of soaking gradually into the soil at the higher elevations and seeping out below all through the year as a feeder to the springs and smaller streams. The result is that instead of a moderate flow extending all through the year there is a flood in the early spring, resulting in excessive erosion of agricultural lands above, the silting up of dams and reservoirs, and the destruction of or great injury to valley lands below by the deposition of vast quantities of soil and gravel washed down from the hills. Then, following the flood, occurs a period of excessively low water or absolute drought, making impossible the utilization of the natural capacity of the soil for storage purposes, and rendering it necessary, in order to utilize the stream for irrigation, to incur great expense in the construction of storage dams and reservoirs, the maintenance of which is in turn made more costly on account of the tendency of the stream to carry an excessive amount of silt during its high stages.

(7) INJURY TO GENERAL BUSINESS INTERESTS.

The vital relationship existing between the lumbering industry and the great industries of transportation, agriculture, mining, and manufacture is unquestionable. The forest furnishes raw material which is indispensable in all, and in addition furnishes a not inconsiderate portion of the traffic upon which the prosperity of the railroads depends. Forest fires, by destroying vast quantities of standing timber and making the natural restoration of the forest impossible over large areas, have seriously lessened the available present and future supply of timber and thus brought about a general increase in the cost of raw material. This has in many cases resulted in decreasing profits, though as a general rule the increased cost of raw material has brought about a corresponding increase in the price of the finished product, the loss thus being transmitted to the general public. Forest fires, however, brought about the direct destruction of a vast amount of private property in the form of buildings and manufacturing plants of all kinds. By destroying in many cases the only available source of raw material, they have made necessary the closing down of business enterprises, thus rendering the money invested in manufacturing plants a partial or total loss. This is particularly true of lumbering operations and sawmills. It is true also to a certain extent of pulp mills, since an expensive plant is of less value where it can be supplied for only a limited period of time than if the supply were sufficient to permit operation for an indefinite period. Fires, by destroying young growth, cut off the future supply and make necessary the earlier removal of plants than would be the case were the forest protected and made to yield a continuous crop.

Nor is even this all. Over large areas the forest is killed and the material made worthless, but the accumulation of millions of cords of this material still remain on the ground, which soon decays and loses its sale value. It takes many years, however, before decay becomes complete. It is material of this kind which furnishes fuel for the terrible fires which occasionally sweep over vast areas. In Michigan the forest fires of 1871 killed great quantities of timber; the fires of 1881 devoured the stuff thus killed a decade before, and were rendered unusually severe because of the vast quantities of débris. For years the areas run over in 1896 will be in danger of renewed and more severe fires. The constant menace of fire is a thing to be avoided, since it imperils not only all the property in its way, but human life itself. The clearing of these burned-over wastes is a severe task, and the settler is not able to partially reimburse himself for his work by the sale of logs, as would be the case were the timber uninjured. As a result of these conditions, settlement in burned-over areas progresses very slowly, even where the land is fairly well suited for agriculture, as it is in most parts of the Middle West. It is stated by the forest warden of Michigan that forest fires have done more to hinder settlement in the northern counties of that State than all other agencies combined.

An additional point not generally considered in connection with the destruction of timber is the fact that the community as a whole is injuriously affected, since its power for development through taxation is decreased. Under our present system of taxation, unimproved, burned-over land must necessarily be assessed at a much lower rate, for purposes of taxation, than when it contained a stand of merchantable timber. This is especially true where the land is not chiefly valuable for agriculture but serves its best purpose as a producer of wood crops. Where settlements exist, an increased burden of taxation is cast upon other forms of property for the maintenance of roads and schools and other incidents to local government. In other words, in order to raise a fixed sum of money the tax rate must be raised in order to compensate for the decrease in the amount of taxable property. This in turn is reflected in a general lowering in the values of all forms of property thus taxed. Where settlements do not exist, development is greatly retarded, since the lack of taxable property renders the construction and maintenance of roads and schools a difficult matter. In fact, in many parts of the country, the combined effects of lumbering and fires has been to bring about the reversion to the State of vast areas of land for nonpayment of taxes. A notable instance in this regard is the State of Michigan. There were in that State, in 1907, 9,000,000 acres of state-tax lands, of which not less than 7,000,000 acres were, according to Professor Roth, cut-over lands, mostly pinery, burned and reburned, with the exception of the swamps. The reversion of these lands to the State withdrew them from taxation entirely, and as a result the development of the counties in which they were located has been exceedingly limited and slow. Had it not been for fires it would, in many cases, have been good business policy for the owners of the land to retain it in order to allow the young and middle-aged growth to attain maturity and be harvested. These lands would in the meantime have been subject to taxation and would thus have aided in the settlement and development of such portions of the region as were chiefly valuable for agriculture. The reforesting of such lands by the State and the payment to the county of a portion of the revenue, in lieu of taxes, offers the best solution of the problem, under present conditions.

Many of the mountain regions of the United States derive a large revenue from summer visitors. For instance, the White Mountains, in New England, and the Adirondacks, in New York, are visited annually by thousands of people from every State in the Union as well as from foreign countries. These regions form vast recreation grounds for thousands of people. Their very existence as summer resorts depends to a large extent upon the beauty of the landscape and the clearness of the atmosphere. The natural beauty of the mountains is enhanced by their forest covering, and when this is destroyed by fire the landscape is rendered bleak and unattractive, thereby lessening the volume of travel. The result is directly translatable into a decreased revenue for the region so affected. What is true in this regard in the White Mountains and Adirondacks is true to an equal or greater extent in many other summer-resort regions throughout the United States.

The relation of forest fires to the naval-stores industry of the South has until recently received little or no attention. Turpentining has been followed by lumbering, so that the disappearance of the virgin forest has progressed steadily. This process has been accelerated by the weakening of the trees due to the burning out of the boxes by grass fires, so that the trees are easily blown down and immediate lumbering becomes necessary. Restocking and natural replacement of the forest have been made impossible over immense areas by the annually recurring grass fires, which destroy the seedlings before they can reach sufficient size to withstand the flames. The condition above described is to a very considerable extent responsible for the fact that the naval-stores industry in the South has never yet been placed upon a permanent basis. The depletion of the forest has occurred in one State after another, beginning with North Carolina and working steadily southward and westward.

The industry has unquestionably been conducted, for the most part, with the intention of obtaining the greatest return for the immediate outlay, irrespective of the waste and wanton destruction of the forests. The fear of exhausting the raw material of the live trees has led to the adoption in some localities of the Herty cup and gutter system. While this system undoubtedly brings about the protection of standing timber and an increase in the quality and quantity of the product, it does not bring about the perpetuation of the forest as such. There is no reason why the lumber and naval-stores industries should not be perpetuated together. Protection from fire in the southern forests would alone bring about the accomplishment of both these objects to a very considerable extent.

More importance is being attached to the second-growth pine than formerly. It is only in recent years that the owners of timber in the Southern States have had an opportunity of noting the value of this second growth and of forming some idea of the possibilities of this character of timber for the development of naval stores. The second growth, following the abandonment of old fields and the cutting away of permanent growth, has developed to the extent of service for turpentining purposes. It is the consensus of opinion among the operators to-day that if fires can be prevented the turpentine industry will be perpetuated, while a few years ago the prevailing opinion was that the turpentine industry would soon be a thing of the past in Florida. It is only recently that naval-stores operators considered it practicable to depend solely upon a second growth for turpentining. Now, however, it is reported that many of them believe that in the years to come there will be turpentine made from second growth alone and that the industry will be as successful then as now. If forest fires can be kept out, there is no question but that this is entirely practicable.

B. CAUSES OF FOREST FIRES.

The fire reports of forest supervisors, while applying only to the national forests, may be taken as a fair indication of the relative importance of the various causes of forest fires throughout the Western States, including the Rocky Mountain and coast regions and the Southwest. Of a total of 2,503 fires occurring in the national forests during the calendar years 1906 and 1907, 641 were reported as having been caused by railroad locomotives, 638 by campers, 458 by lightning, 49 by clearing and brush burning, 43 incendiary, 22 by hunters, and 652 from miscellaneous causes. These figures, while not complete, are sufficient to demonstrate the fact that the principal causes of forest fires in the Western States are railroad locomotives, campers, and lightning. Loss from the first two can be largely overcome by proper precautionary measures. The starting of forest fires by lightning can not be prevented, but it is entirely practicable to greatly reduce the loss by the adoption of some definite plan for extinguishing fires in their early stages.

To be classed with fires caused by railroad locomotives are those caused by donkey engines and sawmills. The loss from these sources, while comparatively small, is great in the aggregate. Since lumbering by donkey engines takes place only on the Pacific slope, the region subject to fires from this cause is limited in extent. Fires from sawmills occur at irregular intervals throughout the entire country wherever the mills are located in the midst of the lumbering operations. That the amount of loss from both these causes as well as from railroad locomotives can be very greatly decreased by precautionary measures has been amply proven by experience. The two most effective means to this end are the use of spark arresters and of oil burners. This has been demonstrated by the experience of the Forest Service in the protection and administration of the national forests.

During the year 1907, 273 fires were started upon the National Forests as a result of sparks from locomotives. There were during that year 32 Forests affected by railroad companies which burn coal and wood as fuel in their locomotives, many of which do not provide their locomotives with spark arresters. The reports upon these fires show that 75 per cent of the fires were started from locomotives not provided with spark arresters. During this same year 65 fires resulted from donkey engines used upon lumbering areas. It is required, however, that these engines be provided with spark arresters, since in all permits allowing the use of steam power a clause is inserted in the final agreement to this effect. It has been difficult to secure the general adoption of spark arresters, since all or nearly all the styles now in use interfere to some extent with the completeness of the draft. Especially on mountain roads does the ordinary type of spark arrester interfere with the steaming power. In many cases engineers have either removed the arresters or screens or else broken them, in order to increase the steaming power, so that the efficiency of the device as a preventive of fires along the right of way was entirely destroyed. The remedy lies in the selection of the best types of spark arresters and in the enforcement of the laws already existing requiring their use. It is, of course, essential that some system of inspection be provided by which it will be guaranteed that the screens will be kept in proper condition. Many types of spark arresters are in use, based upon different theories, and using different sizes of mesh in the screen. The standard spark arrester used by the Pennsylvania Railroad Company has a mesh of two and a half openings to the linear inch, using wire to No. 10 gauge (0.11 inch in diameter), reducing the size of the opening to 0.0841 of 1 square inch. It is believed by the officials of this company that instead of a device for catching the sparks and retaining them long enough to become cold, it is better to break them up into small sizes and throw them as high as possible. This gives them time to cool below ignition point before landing. Observation shows that in general sparks from an engine equipped with a spark arrester will fall inside of 20 feet from the track, while one not so equipped will throw sparks a distance of 50 feet, and on a very heavy up grade to as great a distance as 75 feet.

The importance of keeping the right of way cleared of inflammable material is apparent.

Donkey engines are generally fired with refuse wood and limbs resulting from lumbering operations. This fuel contains more or less pitch, and this, acted upon by smoke and steam, forms a coating over the ordinary old-style screen, very seriously interfering with the draft. When this occurs the engineer usually either removes the screen or, in endeavoring to clean it with a rod or pole, so injures it that it is entirely useless for the purpose for which it was designed. Several improved styles have been designed to meet these difficulties, and the results are most encouraging.

The advantage of using oil as fuel in locomotives in preference to coal or wood, in decreasing the danger from fires, has been clearly shown by the results obtained upon the national forests. There are 912 miles of railroad within the national forests representing 38 different railroad companies. Of these, 25 companies use coal and wood in their locomotives and 6 use oil as fuel. From the 6 railroads burning oil, representing a distance of 82 miles, not a single fire was reported, while 273 fires were started by locomotives using coal or wood. That portion of the Southern Pacific Railroad traversing northern California may be cited as an example. On this portion of the line the coal-burning engines were converted into oil burning, and oil is now used exclusively as fuel. As a result the fire danger is reduced to a minimum, timber fires having been entirely eliminated, and there being no recurrence of the former difficulty with regard to fires in the snowsheds across the summit of the Sierra Nevada.

It is the policy of the Forest Service in connection with timber sales where railroad transportation is required, wherever such stipulation is considered reasonable, to insert in the final contract a regulation requiring the use of oil as fuel for the locomotives during the dry season of the year.

The substitution of electricity for coal as a motive power on railroads also offers great promise for the future safety of the adjacent forest from fire. It is announced that on that portion of the Chicago, Milwaukee and St. Paul Railroad which will traverse mountainous or timbered regions from the Rocky Mountains to the coast, electricity will be the motive power rather than coal. It is reported also that the same action will be taken by the new Western Pacific Railroad in crossing the Sierras in California, and that the Great Northern Railroad is planning to substitute electricity for steam in crossing the Rockies and the Cascades. Local water power will generate the electricity in each case.

Experiments carried on by the New York Central Railroad Company have demonstrated the entire practicability of this course. The extreme cost of transporting coal long distances in mountain regions, as contrasted with the convenient accessibility of water power as a source of electricity in these same regions, will gradually bring about a more general adoption of the example set by the Chicago, Milwaukee and St. Paul Company.

The second great cause of forest fires throughout the West has been the carelessness of campers and of others traveling through the forest. Thoughtlessness, ignorance, and disregard of any but personal welfare have been largely responsible for this condition. Camp fires left unextinguished and lighted cigars thrown away have caused many fires. Many set intentionally have been allowed to spread over large areas. Formerly it was a common practice in many parts of the West for sheepmen to burn over the ranges to open up the way for their herds and to get fresh grass and tender sprouts in the spring. These fires have frequently spread into standing timber and caused incalculable loss. In some cases prospectors have set the brush on fire to make traveling easier and to expose the rocks, thus facilitating the work on which they were engaged. The setting of fires to improve the range or to facilitate prospecting has been practically eliminated so far as the national forests are concerned. Carelessness and ignorance are not so easily reached, but much has been accomplished through education, patrol, and the enforcement of penalties in accordance with law. It is a fact that the worst fires have followed the advent of the whites, notwithstanding the fact that the Indians systematically fired many portions of the country to keep the woods open, and the early Spanish herdsmen in California burned the brush to facilitate travel and open up the country. Fires are also caused by lightning, toward the extinguishment of which in the early days absolutely no steps were taken.

The causes of forest fires named above for the western States are responsible in varying degrees for fires throughout the East South, and Middle West.

In the East and Middle West, while immense damage has been done by fires starting from locomotives, the principal source of danger has for a long time been the clearing of land for cultivation. The periods of greatest danger are in the months of April and May before the leaves have unfolded on the trees, and in September and October after the leaves have fallen. Numerous fires are also caused by the carelessness of hunters, campers, and fishermen. A strict enforcement of existing laws has already materially reduced the loss from these sources, as it has from the clearing of land for agricultural purposes. In many of the States a closed season has been established during which the burning of brush or fallows is made unlawful, or is allowed only under permit issued by firewardens, whose appointment is provided for by law. As a result there has been a very noticeable decrease in the number and severity of fallow fires. In some of the States the improvement has been so great that the damage from this source is very materially less than from fires set by locomotives.

The burning over of so-called blueberry or huckleberry barrens has been another fruitful source of fire damage in many of the Northern and Eastern States. In New England, New York, New Jersey, Michigan, and the mountain districts of Pennsylvania and West Virginia, there are many thousands of acres, worthless for agricultural purposes, upon which, after the removal of the timber and the burning over of the slash, there has sprung up an abundant growth of blueberry bushes, alders, poplars, birches, spiræa, and sweet fern. These lands have in general been considered as public property and recklessly burned over by irresponsible parties to promote the growth of blueberries and to destroy the birches and other plants which would soon shade the ground. The result has been that the fires have year after year encroached more and more on the forested areas, in this way destroying large quantities of valuable timber. Where the burning is done too late in the spring the roots of the bushes are severely injured and a period of ten to fifteen years is required before they regain their producing capacity. In some parts of the country, however, particularly in Maine, the management of blueberry lands has been systematized, and the picking and canning of blueberries has become an industrial operation. Good blueberry land, properly managed, yields a handsome revenue. Economically considered, therefore, the blueberry barrens are in many cases justified. Unregulated burning, however, results in the loss of large quantities of valuable timber, the deterioration of the barrens themselves, and the retention in many cases as comparatively unproductive barrens of lands that would otherwise be producing a valuable crop of commercial timber.

Throughout the Southern States it has been the practice for generations to burn over the woods every year or two. Practically the whole forest burns over annually, usually between December 15 and April 15. Except in the swamps a piece of forest land that has remained unburned five years or more is rare. Practically all the fires are set intentionally.

The principal objects sought to be gained by these fires are: (*a*) To protect turpentine orchards by burning all combustible material at the time of the year when it will cause least injury to the naval-stores industry. Fires are ordinarily regarded as inevitable, and light annual burnings are considered as causing less damage to the mature timber than heavy fires at less frequent intervals; (*b*) to improve the range; (*c*) to protect fences and crops by burning the combustible material on surrounding areas; (*d*) to keep down reproduction and undergrowth and render the woods easy of access at all times.

The fire question is of paramount importance in the Southern States on account of its vital relation to the three forest industries of lumbering, turpentining, and stock grazing. It has been shown by experience that cattle exist quite as well on an unburned range. In fact, many of the more intelligent stockmen have for some time opposed all burning. That these annually recurring fires are resulting not only in the destruction of the present forest but in the prevention of a future one over vast areas is shown elsewhere in this paper. The present deplorable condition of the southern pineries is directly traceable to this source. The only excuse for periodic burning is that it reduces the severity and damage of fires, which it is said are bound to start accidentally if not set intentionally. This, however, is not necessarily true, provided careful and systematic measures are taken to prevent and promptly control all fires.

C. PREVENTION AND CONTROL.

All experience goes to prove that damage by forest fires is practically preventable. This stage of development has already been reached in Europe. For example, of 7,000,000 acres in Prussia, an average of only 1,400 acres, or one-fiftieth of 1 per cent, was burned over each year during the period from 1868 to 1895. This forest contained extensive areas of dry, sandy, pine land, where the fire danger was very great. In the mountainous forests of Bavaria, between 1877 and 1881, only 1 acre in 13,167, or seven one-thousandths of 1 per cent, was burned over. That the same results will in time be obtained in the United States there is no reason to doubt. Many beginnings along this line have in fact already been made, and the results so far obtained, even though frequently on a small scale, offer every encouragement for satisfactory results from future efforts. It must, of course, be remembered that conditions in Europe and in the United States are very different. The large population of the peasant class makes it possible to utilize even the smaller branches and the leaves, thus for the most part removing the medium by which fires are transmitted from one part of the forest to another.

The discussion which has preceded regarding the various forms of damage resulting from forest fires shows conclusively that the nation as a whole can not afford to sustain the immense annual loss which has resulted from this source since before the beginning of the first settlements. The great difficulty has been that while this fact has to a certain extent been recognized by a few individuals and by the Federal Government, it has never yet thoroughly penetrated the consciousness of the people as a whole. Federal legislation has been delayed until vast areas have been devastated almost beyond repair; only a comparatively small number of the States have taken action, and even then the action has for the most part been totally inadequate to meet the situation; in only a pitifully small number of cases has definite action been taken by private owners, whether corporations or individuals. A beginning has, however, been made, and with the inevitable decrease in our timber supplies and the consequent rise in prices will come a constantly increasing realization of the absolute necessity of conserving what remnants are still left of our once magnificent forests. In proportion as this realization grows will definite steps be taken for the perpetuation of the forest upon lands not more valuable for other purposes. Experience in this country, as well as abroad, demonstrates beyond a doubt that the best business policy is one of prevention. The old adage that "an ounce of prevention is better than a pound of cure" holds here absolutely, for two reasons: (1) The cash outlay for preventing forest fires is actually less than for fighting them after they have once secured a start; unquestionably some fires are sure to occur, but when proper precautions have been taken they can be extinguished in their earlier stages at a small cost as compared with the outlay necessary after the fire has gained headway; (2) under the policy of prevention the various kinds of damage already enumerated are for the most part avoided. The saving thus secured is almost without exception many times greater than the cost of protection. To wait until the fire occurs before taking action is to lock the stable door after the horse is stolen.

Fire measures may be classed under three heads: Administrative, legislative, and educative. The aim of the second and third is to secure a more general adoption of the first.

(1) ADMINISTRATIVE MEASURES.

PREVENTION.

Of administrative measures for the prevention of forest fires, the most effective are: Patrol, brush burning, and judicious grazing. For the control of fires the best measures are: Fire lines, back firing, the construction of roads, trails, and telephone lines, and the use of lookout points and observation towers.

PATROL.

Of preventive measures by far the most important is patrol, since without it the others can prove of but little avail. The necessity of maintaining a regular patrol during the fire season can not in fact be overestimated. To leave the extinguishment of fires until they have grown to such proportions that they attract public attention is to defeat the object sought, since by that time the damage sought to be avoided will already have taken place, at least in part. The superior efficiency of a well-organized, paid fire patrol over volunteers or local officers appointed as fire wardens has been thoroughly demonstrated wherever it has been tried. The size of patrol districts depends first upon the funds available for the purpose, then upon the topography of the country, the amount and character of the timber, the amount of combustible material on the ground, the character of the season, the amount and sources of fire danger, and the efficiency of the patrolman. On the national forests the area of ranger districts varies from 40,000 to 200,000 acres, the former figure applying to the southern California forests, where there is extreme danger from fire and where the importance of the forest and ground cover as a watershed protection is greater than anywhere else in the United States.

In connection with the prevention of forest fires by patrol the following statement by Col. W. F. Fox, of the New York State Forest, Fish, and Game Commission, is of interest as showing the difficulty presented by one phase of the problem in the United States:

> The problem presented by the railroads is the most serious of all. We hope now to compel them to patrol their roads thoroughly during the dangerous seasons. Still, railroad patrols will not entirely eliminate the fires caused by locomotives. Even if we were to put them on one man to a mile, a fire could start between two of them in a dry time and attain dangerous headway before it could be noticed. There are only two remedies for railroad fires:
>
> 1. The forest floor along the line of the railroad must be kept as clean as in Germany.
>
> 2. The companies must use petroleum or electricity on their locomotives.
>
> The time has come when the State of New York has got to choose between its railroads and its forests. I am satisfied that we can not have both unless some stringent measures are enacted.
>
> As you are aware, the German forests are traversed by railroads to as great a degree as our own. Their immunity from fire is due to the fact that there is nothing on the ground aside from leaves that will burn; but the forests along our railroads are so filled with inflammable material on the ground that in a dry time a spark is very apt to flash them. During the drought of last year we were about as helpless in the matter of railroads as the superintendent of a powder mill would be if he allowed visitors to travel through his works, each one with a lighted cigar.

BRUSH BURNING.

In general, the hottest and most difficult fires to control are those which occur in the slash resulting from old lumbering operations. The removal of this menace is essential to the success of any operation looking toward the perpetuation of the forest. Of the various methods of reaching this end, one of the most effective is the burning of brush or slash either at the time of the lumbering operation or at its conclusion. Unfortunately, experiments to determine the practicability and cost of this method have, with very few exceptions, been carried on only upon the National Forests. The following statement is taken from the Forest Service circular entitled "Suggestions for the Disposal of Brush in the National Forests," by J. S. Holmes:

> The piling and burning of brush on the National Forests has been required for the purpose of fire protection, but experience has shown that it is not always advisable. Every case should be considered separately and the question of brush disposal settled according to the special needs of the area in question.
>
> ADVANTAGES OF BRUSH BURNING.
>
> The greatest advantage of brush burning is the protection it gives against fire. In many cases brush burning is the only practicable safeguard against fire. After the average lumbering operation the ground is covered with slash, scattered about or piled, just as the swampers have left it. This, in the dry season, is a veritable fire trap. Probably 90 per cent of all uncontrolled cuttings are burnt over, which retards the second crop at least from fifty to one hundred years and perhaps permanently changes the composition of the forest. Fires may be set by loggers while still at work on the area or several years after by lightning, campers, or locomotives. By piling the brush and burning it in wet weather or in snow, when there is no danger of the fire spreading, all inflammable material is removed, and the second growth can come up without serious risk of being destroyed. Even where only part of the brush is burned and the rest is piled, as when the piles in open places, along ridges, streams, or laid off lines are burned, very much is gained in case of fire, since these cleared lanes form bases from which a fire may be fought.
>
> Besides lessening the danger from fire, brush burning has certain minor advantages. When the brush on the ground is removed it is much easier for rangers and others to ride or walk through the forest. This may be very important in case of a fire or in rounding up cattle. It is also much easier to cut and handle ties, cordwood, or other timber which may later be taken from the cut-over area if the slash is out of the way. By piling and burning the green brush as it is cut from the trees by the swampers, as is now being done in Minnesota and parts of Montana, the ground is cleared and skidding is made easier and cheaper. Again, careful piling and burning of brush improves the appearance of the forest. There is nothing much more unsightly than a recently cut-over area where no attempt has been made to dispose of tops and lops. Near towns or resorts and along roads or streams frequented by tourists this point should be carefully considered, but as a general rule the utility of the forest should not be sacrificed for beauty.
>
> DISADVANTAGES OF BURNING.
>
> The disadvantages of burning brush are many and, with the one exception of protection from fire, far outweigh the advantages. If protection can be had in some other way, as with more efficient patrol service or more stringent laws, the practice should in many cases be abandoned. In many places, especially in the yellow-pine type, the best, and often the only, reproduction comes up under a fallen tree top or other brush. Where there is little of the old stand left, the straggling open top protects the seedlings from the direct heat of the sun. Yet brush not only protects the seedlings from the sun, but, what is more important, the leaves and broken twigs form a cover which retards evaporation of moisture from the soil. Over the greater part of the West the soil dries out very rapidly during the dry season, and this seriously retards or even prevents the growth of seedlings. Even in the moister regions, such as that of the Engelmann spruce type, it is very necessary to conserve the moisture in the soil after logging to prevent the remaining trees from being killed through lack of soil moisture. A third reason why seedlings so often come up only under the down tree tops is that they are protected from stock. Next to drought, sheep are perhaps the most serious menace to reproduction, and though it would be best to keep all stock off the area for several years after logging, in many cases this is not practicable, and on many areas the leaving of the tops on the ground is the only way to protect reproduction from injury.
>
> In many places after the timber has been cut off gullies and washes start in the old wheel ruts, log slides, etc., and these and other forms of erosion can best be prevented by leaving the brush on the ground, either laid in the incipient washes or scattered over the soil that is likely to wash. Brush burning de-

stroys the valuable soil cover, and on the spots where the piles are burned the soil is loosened, which renders it even more liable to erosion.

It is well known that where the forest is burned each year the soil becomes poorer and poorer, because nitrogen, the chief fertilizing ingredient of the soil, is given off in the smoke, and only the mineral elements go back to the soil in the ashes. And, what is more injurious, the humus, i. e., the decomposed vegetable matter in the top soil, is destroyed. In burning brush after logging all the fertilizing and humus-forming leaves and twigs are destroyed just when most needed, for another good crop of leaves can not be expected for many years.

The burning of brush not only removes from the soil its natural manure, but renders it unfit for the germination and growth of seedlings. This is especially true of Engelmann spruce. Douglas and white fir also in the Southwest will not come up after fire. The area of ground covered by piles for burning varies according to the type and to the density of the forest, but an average of from 5 to 10 per cent of the total area is thus made nonproductive. If full reproduction could be procured on the rest of the area, this would make very little difference, but where reproduction is scattered and hard to procure, as in the Southwest, it would probably make considerable difference in the final stand.

The added cost, both to the lumberman and to the Government, is another argument against brush burning. The cost of piling brush has varied all the way from 15 cents to $1 or more per thousand, with an average of 40 or 50 cents, while the cost of burning may be from 5 cents to 25 cents per thousand, averaging about 15 cents. By abandoning the practice of brush piling, this 60 cents a thousand will not be entirely saved, as is claimed by some, for the brush will still have to be lopped and disposed of in some other way, which will cost, it is estimated, at least half as much as piling and burning. But even a saving of 25 or 30 cents a thousand is a strong argument against the practice.

Thus, from a silvicultural viewpoint, the disadvantages of brush burning far outweigh its advantages. Yet, as a general policy, it seems unwise, until other methods have proved their efficiency, to abandon brush piling and burning to any great extent at present. The fire danger is a known quantity, and though it is being reduced each year it is still a menace. Therefore changes from the present practice should be made with caution. Brush piling and burning is certainly not advisable in all cases, and extensive experiments should be made to determine what is the best method of brush disposal for the different types and conditions.

Brush Piling and Burning.

The cost of piling varies with the cost of labor, the methods of logging, the type, the topography, the kind of trees cut, and the time of year it is done. A few figures will illustrate this variation. In the yellow-pine type in Montana an addition to the swampers' wages of 15 cents a thousand would, it is said, enable them to pile the brush, as they have to handle it anyway. Usually, however, the piling is done by a separate crew. Much of the work is thus duplicated. In yellow pine in the Southwest, brush piling costs from 45 to 50 cents, while in Montana it can be done for 25 cents. One operator in lodgepole in Montana says it is cheaper for him to pile than not to, because he can get his skidding done so much cheaper, yet on other operations it has cost from 50 cents to $1 a thousand, depending on how thoroughly it is cleaned up. In the sugar-pine yellow-pine type of California, the cost of piling averages from 25 to 35 cents, while the cost in the Douglas fir type, in Montana and Idaho, averages about 40 cents, and in Engelmann spruce type the cost is only about 25 cents a thousand. It is certain, however, that the cost of piling will everywhere be materially reduced when the operators begin to look on piling as part of the swampers' regular work and not as an entirely separate job.

Dry brush should never be burned during the dry season, unless absolutely necessary for the suppression of an insect invasion. Green brush in some places may be burned at any time, but as a rule it is unsafe to burn it in dry weather. The best time to burn brush is in the fall, just after the first snowfall. Then the piles are dry, and there is no danger that the fire will get beyond control. Brush may also be burned at the beginning of or during the rainy season, when the ground is damp enough to prevent the fire from spreading, and the brush dry enough to burn readily.

The cost of brush burning varies like the cost of piling. It varies even more in the same localities, with weather conditions and methods of piling. Brush that can be burned for 10 or 15 cents a thousand at a favorable time, as just after the first snow, will cost 5 or 10 times as much to burn in dry weather, or when the piles are very wet. Brush can be burned more easily the first fall after cutting than it can the second year, when many of the leaves have fallen off. Brush burning has been done for 13 cents a thousand in lodgepole, in the Medicine Bow National Forest, while it has cost 22 cents in similar timber in the Yellowstone, and estimates of 40 cents a thousand have been made for it in the Rockies. It is generally admitted that brush can be most economically burned by the same people who pile it. Recently several contracts have been made in which the purchaser of the timber is required to pile and burn the brush under the direction of forest officers, as has been the practice in the Minnesota forest for some time. This will lighten the total cost, and when the weather allows the brush to be burned, as logging proceeds, the cost of burning will be offset by the subsequent reduction in the cost of skidding.

Piling Without Burning.

Brush piled properly, even though it is not burned, is a great protection to the forest. Inflammable material is removed from among the living trees, and should a fire occur it would be much easier to fight. This is especially true where reproduction is dense. Where openings are scarce piles should be made in the most open places, and may be larger than those made to be burned.

Ground Burning.

Where clear cutting is practiced and fire assists the reproduction that is wanted, ground burning is sometimes advisable. The slash is left scattered as in primitive lumbering operations, and after an efficient fire line has been made around the area it is burned off clean. The fire line should be thoroughly cleaned up before the area is fired. Great care will have to be exercised to prevent the starting of a crown fire, which can not be controlled even with wide fire lines. The brush should usually be fired against the wind, and should the wind change after the fire is started the brush on the opposite side of the tract should be back fired. This method is the only practical way to secure reproduction of desirable species in some parts of the country.

Lopping and Scattering.

Where it is best to lop the tops and scatter them over the ground, the lopping should be done thoroughly, so that the top logs and larger branches will lie flat on the ground. If the object is to prevent erosion, the brush should be scattered or roughly piled where washing is most likely to occur. If washing has already started in wheel ruts, log slides, etc., brush should be laid in these as compactly as possible. If good-sized gullies have formed, it is usually better to put the brush in them in compact piles, filling them from side to side, than to scatter some brush all along them. If the chief object in scattering the brush is the conservation of moisture, it should be scattered evenly over the ground within reasonable distance of where it is felled, care being taken to keep the brush at safe distance from living trees. Where brush is scattered, fire lines should be made at intervals by piling and burning the brush in lanes 200 or 300 feet wide. This diminishes very greatly the danger from fire, by isolating different areas in the forest and giving places where back firing can be started. The cost of lopping and scattering brush in this way has not been determined, but it is thought that it can be done for from 50 to 75 per cent of the cost of piling and burning.

Grazing.

The fact should not be overlooked that judicious grazing in coniferous forests is a benefit rather than an injury. Not only does it not prevent reproduction where the range is not overstocked, but it aids very materially in making it possible to protect the forest from damage by fire. Where the range is not utilized, or incompletely so, a thick covering of dead grass accumulates on the ground, which burns readily, carrying the fire over large areas, destroying young growth, injuring middle-aged and mature timber, and setting fire to any inflammable material that may be within reach. Where there is a sufficient amount of dead timber on the ground to hold fire, the living trees are usually killed and partial or total loss of the property results. On the national forests throughout the Western States protection from fire has been most difficult on grazing lands which could not be utilized on account of lack of springs or streams for stock-watering purposes. A good example of the damage resulting indirectly from this condition is the Paulina Mountains fire, which burned from August 2 to 23, 1908, in the Deschutes National Forest, Oregon. There is no surface water in or near the vicinity; it has, therefore, not been possible to utilize the range, and as a result the ground was covered with a heavy covering of dead grass under the growing vegetation. The cause of the fire is attributed to lightning.

The region where the fire occurred is remote from settlement and before help could be secured to fight the fire it had assumed great proportions, covering a front of 40 miles. It was 50 miles to a base of supplies and 16 miles to water. Men had to be brought distances varying from 50 to 150 miles, and over 100 were employed in fighting the fire. Though 240,000,000 feet of green yellow pine was killed and 3,000,000 feet of dead pine destroyed, an immense amount of timber was saved that would have been destroyed but for the efforts of the forest officers. The point, however, is that had the region been moderately grazed the large amount of dry grass would not have been present on the ground, the fire could not have traveled as it did, and the damage would have been but a small fraction of that which actually occurred. An additional point is that where stock is grazed the presence of men to care for them is required; and these men are invaluable in aiding forest rangers and local residents, if there be any, in discovering and extinguishing fires before they gain headway. The development of water on dry ranges, in the form of wells or springs, and its retention in troughs or reservoirs, for the use of stock, would go a long way toward making possible the prevention and control of forest fires in remote and inaccessible regions. This is a strong argument in favor of the policy which the Forest Service has adopted of developing the range as fast as the necessary funds can be made available.

REMOVAL OF DÉBRIS.

In many cases it is entirely practicable to prevent damage to standing timber in case of fire by removing the combustible material from the base of the trees.

Mr. T. B. Walker, one of the largest owners of timber lands in northern California, gives the following description of the method adopted upon some of his tracts:

> In the spring of 1902 I sent a crew of men into a large tract of timber on the headwaters of Fall River, in northern California, who were known as the "fire brigade." They were fully equipped with teams, camping outfit, tools, etc. After establishing their camp in a particular locality the section was divided into 40-acre tracts, and each two of eight of the men went upon four separate divisions and systematically began the work of clearing away around the foot of each tree all the needles, leaves, cones, brush, limbs, pieces of stubs or logs that lay against or near the roots of the tree. Each was supplied with tools, one carrying a shovel and ax, the other a shovel and crosscut saw. With the shovel they scraped away all the loose materials to the distance of several feet from the tree, and with the ax and saw they chopped or sawed any larger pieces, which were then rolled away. All trees having burned spots or hollow places, after clearing out and away from them all the leaves and loose materials,

loose dirt was thrown against the spots and the hollow places filled, so that when another fire came they would be protected. The bark of these trees is very thick and furnishes a very natural protection against the running fire. It is only where an extra amount of fuel is accumulated against the side of one of them that it can be burned through sufficiently to injure the tree. But when a burned spot is once formed the pitch runs out and forms a coating or bunch that is very combustible when fire again comes, if it reaches to it. But by means of clearing away the material and covering up the pitch and hollow spot the bark will re-form and cover the damaged place, so that future fires will do no damage until another accumulation of fuel, as in the original burning.

There is hardly any such thing as a sweeping fire in California in the uncut forest that consumes or destroys any considerable number of trees. It is only through a gradual process of damage at the root of the tree in the manner above specified, where, after a burned spot is once formed, the next fire enlarges it through the large cavity formed, which in the course of years enlarges so as to leave only a shell of the trunk of the tree, and finally to so burn it away that it falls and throws a large top with its leaves and cones alongside of other trees.

This great amount of fuel renders the trees against which it has fallen liable to the same kind of process of gradual and sometimes immediate destruction when the next fire occurs. The fire brigade is expected to clear away all such fallen tops to whatever extent they endanger other trees. A tree may be injured many times by having spots burned where all of them may gradually be healed over without much permanent injury to the tree, and where a spot is formed is enlarged from time to time by repeated fires, it may take a great many years, a quarter or half a century, perhaps, or more, to destroy the tree.

Now, at any time from the foundation of the burned spot to the time that the tree is burned down, this process will protect it from further damage, and if there is enough wood to keep the tree from blowing over, the process of repair and growth will be resumed as soon as the ravages by fire are stopped.

METHODS OF FIRE CONTROL.

Fire lines are one of the most effective means of controlling serious fires. Their value, however, depends largely on the character of the ground cover, and in some regions their use is not advisable. Moreover, their width, location, and manner of construction vary with local conditions, all of which must be decided by local study on individual tracts. In the southern pineries, and wherever the aim is to stop grass fires, the main fire lines should be plowed strips from 10 to 30 feet wide, with a narrower parallel line some 40 to 100 feet distant. The space between the two lines can often be burned over to great advantage. In timber land with a brushy undergrowth fire lines are usually impracticable, but if made should be 40 to 100 feet wide to be at all effective—the wider the better. Fire lines on cut-over lands are often of high value, and should be of varying width in accordance with the condition of the inflammable ground cover. Cleared or burned strips 100 or more feet wide are often essential. In pure brush growth, such as is commonly known as chaparral in California, fire lines are very essential, if fires are to be quickly controlled. They should be widest in "saddles" and where the brush is densest, and of minimum width on the crests of sharp ridges. A width of from 15 to 50 feet or more is usually advisable. The brush should be cut off close to the ground and the roots grubbed out if possible. All such lines should be connected with trails.

Much depends on the location of fire lines. They should not be expected ordinarily to stop a fire, but rather serve as an indispensible vantage point from which to back fire or to beat out flames which jump over. Fire lines should take advantage of topographical features and be located where fires are naturally reduced in their progress or severity. This is usually on the crests of ridges or where the brush or forest is open or the ground bare. An important consideration in all fire-line construction is to plan for the removal of all dead stubs for a distance of at least 200 feet on each side. In case of fire these stubs ignite readily, and the wind carries sparks and firebrands from the tops for long distances.

Closely associated with fire lines is the question of back firing, and plans, based on local conditions, should be made for this use of fire in fighting fire. Back firing should be resorted to only when absolutely necessary, and never save under competent supervision.

If fire should get a good start in old slashings or logging works, it might be useless to make a fight until it reaches a skid road or stream, or possibly green timber. If it can not be checked until it reaches green timber, it is best to go back far enough into the timber so that the heat and smoke will not drive out the fire fighters. If there is no road or skid road in the timber where a stand can be made, and if the ground is fairly level, a trail should be cut around the head of the fire from 10 to 20 feet wide, and brush, rotten wood, moss, etc., cleaned out and piled on the side next to the fire. A back fire should then be started. In back firing it is most essential to see that the fire does not creep or blow back across the trail. It is dangerous to back fire unless enough help is available to control it. When fire strikes the green timber it will probably burn some tree tops, but when the tops and brush along the edge of the timber have been burned, it will die down and creep in the moss and brush on the ground and it can then probably be stopped at the trail. If, after the fire has died down, there are any dead snags left standing with fire near the top, they should be cut down.

Fire rushes uphill, crosses the crest of the hill slowly and is more or less checked in traveling down. If the fire is running uphill, especially with the wind behind it, it may be impossible to handle it until it reaches the top. If such is the case the best place to cut the trail is just beyond the crest of the hill, where there will be less smoke and where the fire will naturally be checked in running downhill.

The fire should be watched until it is entirely out. The first fire burns above the surface of the ground, and there is apt to be fire left smouldering underneath for days. The trail should be watched as long as smoke can be seen, and as soon as it cools down what fire there is left should be dug out. Dry sand or earth is usually as effective as water (and much easier to get) when thrown on a fire. Fires burn faster in the heat of the day and are more easily controlled at night or in the early morning.

In all plans of fire protection provision must be made for an emergency fire-fighting force. The labor arrangements at the mill or in the camp must be studied, and a force of competent men selected who can drop everything at a moment's notice and proceed to a fire. This force should be made up of men who can be spared temporarily without shutting down any part of the mill or interfering with logging operations. One or more experienced men should be designated to act as leaders of the fire-fighting squads.

Plans should be made for storing suitable fire-fighting tools at readily accessible points. One set should be at the mill or camp where the emergency force is working, and others in settlers' cabins or special tool houses on different parts of the tract. The location of these sets of tools should be determined by a field study. The tools usually needed are axes, spades, rakes, and buckets, and canteens for the personal use of the men.

Where fires frequently start along logging railroads it has occasionally been found advisable to equip a flat car with a water tank and force pump for use in extinguishing fires near the track. This, however, is rarely necessary, but should be considered. A more effective means of preventing the spread of fire from locomotives is to clear or burn a strip 200 or more feet wide on each side of the track. These lines should be made part of the general fire-line system.

Trails are indispensable on ordinary forest tracts, in order that all parts may be readily accessible. In connection with fire protection they are needed by patrolmen, and in order that fires may be reached without delay. Wherever possible trails should be laid out with the contingency in mind that they may at some later date be developed into roads.

On large holdings the location of lookout points should be decided upon if their use is advisable. They should be located, if possible, on the regular trails. The value of lookout stations will be determined largely by the topography and size of the tract. They are naturally of the greatest value in mountainous regions and practically useless in a level country. Sightly points should be selected for these stations, and provision made when advisable for cabins and for permanent observers during the season of fire danger.

In connection with the trails and lookout stations the construction of telephone lines is of great value, since by this means it is possible to secure help quickly in case of fire without the necessity of the patrolman leaving his district for that purpose. The existing means of communication, the need of call boxes along the trails, and the necessity of giving the men at lookout stations direct communication with headquarters should be the determining factors in locating telephone lines.

FIRE FIGHTING BY REGIONS.

It is impracticable here to include detailed and definite instructions to cover local fire-fighting problems; on the other hand, conditions so vary that no set of rules can be given that will apply universally. Eastern and western forests differ, and there are regional differences within these two great areas. Altogether there are eight distinct areas as regards forest fires, each of the eight having peculiar features that distinguish it from the others. Those in the East include the spruce forests of the Northeast; the woodlot that is characteristic of the New England and Middle Atlantic States, and the Ohio Valley region; the hardwood forests of the Southeast, including particularly the Southern Appalachian region; and the coastal pine belt of the Southeast and South. Then there is the Lake States region, and in the West the Rocky Mountains, the Pacific Northwest, and California, particularly the southern part.

Fighting fires in the Northeastern States.—The principal forest regions of the Northeast are characterized by dense stands of conifers, and by open hardwood stands with heavy undergrowth. The ground is covered, for the most part, with a thick layer of humus or "duff," which may carry a fire for a long time and not show it. Forest fires in this region are most common in early spring—April and May—

but are likely to occur also, though with less frequency, in the early fall—September and October. In the spring the ground is covered with a thick layer of dead leaves. With the advent of the warm sun and the south wind these become so dry that they ignite easily and burn quickly, with a blaze fierce enough to communicate itself to the dry refuse of old cuttings and to dead trees.

Two classes of fires are recognized in this region, ground and crown fires. Where there is only a light surface fire, the most common and least expensive way is to put it out with green branches, wet sacks, or wet blankets. This method is effective if the fire is attacked early enough, and if great care is used to see that the fire is actually all out and not driven from the surface down into the duff.

Where the fire is more severe and there is plenty of water, a common method is to institute a "bucket brigade," whose members pass buckets of water from a stream to the fire line. The water is rarely used against a main fire, because there it would be largely wasted, but rather to quench numerous small blazes that are started by sparks from the big one.

Where water is unavailable, sand or earth is thrown on the small blazes. This is harder work, but is more effective, unless the earth used is composed of humus or vegetable mold. In that case it apparently smothers the fire, but eventually adds fuel to it.

The best way, however, to stop a ground fire, and often the only sure way, is by trenching. This is simply digging down to the mineral soil and throwing the dirt toward the fire. This is a costly and a hard task; to be successful it must be done so far ahead of the fire that the mineral soil can be reached before the fire gets a chance to cross over. A faster method, but not so sure, is to dig holes in a line a rod or so apart and spread the dirt along the ground between the holes. Sometimes furrows may be plowed or fire lines may be cleared ahead of an advancing fire.

Crown fires can not be attacked directly unless the fire is small and the conditions unusually favorable. The flames travel so rapidly and jump such long distances that nothing can be done, except a long way in front of them. Lines may be cleared along the edges of the fire to prevent its spread laterally. Back firing is an extreme to be made use of when all other methods fail, and then only under the direction of an experienced person. The danger, particularly when there is a wind, is that the back fire may spread and add its fury to that of the original fire. When it can not be started from and held to a fixed line and forced back toward the main fire, a modification may be adopted to burn over an extended area far ahead of the on-coming blaze, which will go out from lack of fuel when it reaches the burned-over portion. In order to minimize the danger of having the precautionary fire get beyond control, the area to be burned may be divided into small sections, and each fired separately. This plan is analogous to the dynamiting of blocks of buildings to stop a city conflagration, and should not be resorted to except in extreme cases where valuable property is at stake.

Railroads in the Adirondacks use special devices for fire fighting. The Rumford Falls and Rangeley Lakes Railroad in western Maine has hose of extra strength, which, attached to a locomotive's pump, sustains a pressure of 90 pounds, sufficient to throw a half-inch stream about 100 yards. The jet of water trained on a tree is strong enough to tear off the bark, and will shatter burning stumps. It has been used with very satisfactory results.

The fires in the Rangeley Lake region of 1903 were generally fought by crews of about a dozen men, whose leaders had a code of signals by which the work could be correlated and reenforcements sent to points of particular danger. Usually the crews were called out at 3 o'clock in the morning and continued fighting until 1 o'clock in the afternoon, when the wind was so strong that no work could be done, except by scouts ahead who kept little fires from starting in advance of the big ones. Then in the evening when the wind went down with the sun, and the fire largely changed back to a ground fire, work would be resumed for a few hours until the night winds came up.

Protection of the woodlot.—It has been estimated that one-third of the total stand of timber in the United States is in farmers' holdings. The woodlot is thus an important part of the forest resources of the country.

The successful protection of the woodlot from fire requires three conditions: Proper organization, efficient watching, and facilities for fighting fire. By organization of a woodlot for fire protection is meant the establishment of such a condition that fires may most easily be prevented from starting, and that fires which do start may most readily be extinguished. The measures usually practical in this woodlot organization are, first, the disposal of tops and dead brush, and, second, a construction of fire lines. A fire in leaves may be put out entirely, but if tops, old logs, and snags lie scattered about, the fire may smolder in them for a long period and remain a constant menace after the main fire is out. It is especially desirable to prevent the accumulation of inflammable trash near roads and paths where smokers and hunters are liable to set fires.

The best fire lines for the woodlot are roads and paths. Their first purpose is to make the different parts of the woods readily accessible. In a city the effectiveness of a fire department depends on the degree of quickness it can reach a fire. In the same way, the forest traversed by roads and paths by which an incipient fire can be reached quickly is in the best condition for protection. Roads and paths will check an ordinary fire. Many fires are absolutely stopped by a dirt road, and small fires will not cross a dirt trail. If back firing is absolutely necessary, it is best done from a road or path. An opening in the forest may be a vantage point from which to fight fires, but as a check to fire it is only slightly better than no opening unless cleared entirely of inflammable material. Ordinarily, if the roads are adapted to use as fire lines, and if there are roads or trails near those boundaries where danger exists, the woodlot is well organized.

Constant watchfulness during the danger season is absolutely necessary. A woodlot that is not watched is not protected. Usually a woodlot is in close proximity to the cultivated portion of the farm, and it involves very little additional trouble to watch for fire. During very dry periods it is sometimes desirable to actually patrol a lot two or three times a day.

It is necessary not only that the fire be discovered quickly and reached quickly, but there must also be ready facilities for attacking it. The watcher must have the necessary tools readily accessible,

i. e., axes, shovels, rakes, and water pails. He should also be able to secure help quickly in case he can not handle the fire alone. The best system is to have a cooperative understanding among a group of neighbors to assist each other in case of fire.

The South.—Broadly speaking, the fires within the mountain region of the South are surface fires which consume only down timber, young growth, slashings, leaves, and other forest litter. These fires are set by careless hunters, by sparks from locomotives and sawmills, or intentionally by cattle owners to improve (as generally erroneously believed) the spring grazing.

Whatever the cause of the fire, each owner of forest land should use every effort at his command to extinguish the fire at the earliest possible moment. If taken in time at the early stages, one man can often beat it out with brush or surround it by raking away the leaves. If delayed a short time, the assistance of neighbors will be required, but usually the efforts of such organized fire fighters are directed not so much to extinguishing the fire as to turning it aside from the farm buildings, fences, or dry crops of the owners directly interested at the time.

In a mountain region large and small owners in a section of country, say of a county or a watershed of a stream, should combine for protective measures in preventing and fighting forest fires within the section. Such an organization should employ a fire warden and one fire guard for about each 10,000 acres of land. The duties of the fire guard would be to patrol or keep a lookout from vantage points during the dangerous season of early spring and fall and seasons of drought. Behind the fire warden and guards every owner of timber land within reach of a reported fire, with his employees in logging camps, sawmills, farms, or tenants, should be prepared to go to the fire immediately and stay with it until extinguished.

Fire usually travels slowly in the hard-wood region of the mountains, and a line of men with rakes, shovels, and brush should easily control any ordinary conflagration. With a brisk wind and a rapid fire the line of men should retreat to the next stream, dry run, or crest of a ridge and make a fire line about 5 feet wide by raking away the inflammable litter. Back fires should then be set along the side of the line toward the fire, with the men keeping watch to see that it does not cross the line.

The cost of this system of protection should be distributed among the owners of timber land within the protected areas in proportion to the acreage of their respective holdings. Where patrol is only necessary for short periods two or three times a year the expense should not be more than a fraction of a cent per acre, and is more than justified by the amount of timber it may save from fire left to run until it burns itself out or is extinguished by a chance rain storm.

Throughout the rolling hills of the Piedmont Plateau, contiguous bodies of large timbered areas are infrequent, and the timber is generally confined to large wood lots and pasturages of plantations. Here it is more clearly the problem of the individual owner to take care of the fires arising on his own land, but, again, the cooperation of timber-land owners in each community or settlement for mutual protection would be a thousand times more effective in preventing the disastrous spread of a small fire, neglected, perhaps, for the reason that it was not on the land of the one who observed it.

In the turpentine belt or longleaf-pine region dry grass in the open woods is fired every winter to improve the grazing and to prevent fires later on during the turpentining season. In this region the custom of annual burning is more firmly established than in any other forest region. The problem of fire protection is made more difficult by the fact that natives hold to the custom as an hereditary right, lumbermen are indifferent, and turpentine operators care only to protect their four crops of turpentine in the easiest manner.

The problem resolves itself into a remedial campaign of education relative to damage by forest fires, enactment and enforcement of suitable state fire laws, creation of an organization of state fire wardens, and guards who will do something, and persistent personal effort of each state forester in stimulating public sentiment against setting fires in woodlands.

If enough interest can be aroused, owners of adjacent timber lands may be prevailed upon to band together for fire prevention and protection, each defraying his proportional share of the expense.

Fire protection in the Lake States.—With the possible exception of the southern pine region, there exists nowhere a greater apathy regarding forest fires and less real effort to prevent them than in the Lake States—Minnesota, Wisconsin, and Michigan—this in the face of the fact that a major part of the property fire loss and more than three-fourths of the deaths have occurred in this region. Disaster, such as that of 1908, does not seem to offset indifference and ignorance; even where state laws are good, they are useless unless enforced and supplemented by the efforts of landowners.

In the Lake States fires can for the most part be completely suppressed with reasonable expense. The most destructive fires always occur in cut-over areas of slash, and such fires may in a high wind spread into the crowns of young pine and balsam. So great is the danger of fire after logging that if fire protection is to be attempted, the tops must be burned.. This can be done during the skidding, even with snow on the ground, by piling the tops on fires as the swamping progresses; or the tops can be burned early in the spring before the ground is dry enough for fire to run.

With the slash burned, subsequent fires will take the form of low surface fires consuming the dried grass, weeds, and small brush of from one to three years' accumulation. These fires must be absolutely prevented if a second crop of timber is to be grown.

To do this the owner must resort to two measures to supplement the state fire laws, namely, the employment of fire patrols and the construction of fire breaks.

Streams, roads, and even trails may be used as fire breaks. A high wind will drive fires across the best fire breaks, but small fires frequently burn out along a break or road. The purpose of breaks should be, not to mechanically prevent the crossing of a fire, but to give the fire patrol a chance to fight an advancing fire successfully.

The worst fires may be stopped along a fire break by back firing. It is, therefore, to supplement the efforts of the fire fighters that breaks should be made.

Where natural features or roads are absent fire breaks can often be cheaply constructed. On the sandy plains of the Michigan state forest reserves strips 20 feet wide are fully plowed, with no effort to grub the stumps, at a cost of $20 to $30 per mile. The first plowing lasts two years without renewal.

In hard-wood forests or white pine, with much underbrush, plowing is expensive and inefficient. Here two parallel strips may be cleared a few feet wide by brushing and raking, and the space between burned, the width being from 25 to 100 feet, according to the danger. Railroads should burn a strip along their tracks as wide as their right of way, and 200 feet would be safer.

A mounted ranger can patrol a township of land and is often called on to guard much larger areas. If on foot, there should be two and preferably three or four men to a township, depending on the value of the property to be protected. The larger and more compact the holding, the smaller will be the expenses per acre for fire protection.

For fire fighting in most of the Lake State regions water is not available. The long-handled shovel and the use of sand will be effective against ground fires. For the direction of a force of fire fighters, and for the subsequent handling of back fires whenever they become necessary, a ranger with some experience is indispensable. The employment of one or more of such men will have an educative and restraining influence in the matter of careless setting of fires. The total cost of fire protection by these means should not exceed 10 cents per acre annually on tracts of 10,000 acres or more.

Fire control in the West.—In the western part of the country, three different types of forest roughly differentiate the methods of fighting. These types may be described as the Rocky Mountain, the Pacific Northwest, and the California.

The Rocky Mountain region.—In the Rocky Mountains fire is much dreaded from the beginning of the dry season until the first storm that presages winter. Because of the character of the country it is particularly hard to locate a fire that is started. The column of smoke that appears to be just over the first ridge may prove to be many miles away past peaks and canyons. Where a fire gets started and it is impossible to extinguish it, as is generally the case, all effort should be centered on confining it to the smallest possible area, or to the area containing the least valuable timber or upon which the least damage will be done. It is practically impossible to extinguish a fire of any extent by the application of water, and wholly impossible to beat out one, as in the case of a grass or prairie fire. The only effective method in this region is trenching, which consists in the removal of all duff and litter down to the mineral soil, in a strip about two feet wide. It is, in effect, ditch digging, which may be done rapidly and with comparative ease by the use of shovels, on soil covered only with humus and free from brush and rocks. Upon ground covered with huckleberry brush and other similar growths, and where the surface is rock strewn, the task becomes slow, tedious, and difficult, and the shovel must be supplemented by the mattock and pick.

To make trenches immediately adjacent to the fire front is worse than labor wasted. It is unnecessarily hard on the fire fighters because of the heat and the danger from falling trees. Moreover, these trees falling across the trench carry the fire beyond it, and there is always the possibility of overlooking particles of burning refuse and limbs that will carry the fire ahead. The location of the trench then becomes a vitally important point, and one to which the man in charge must give his attention at all times. Fortunately, the wind can usually be depended upon to come from a definite direction during the daytime, with a lesser opposite motion at night, beginning about sunset, and not reviving until about 10 in the morning of the next day. No matter what the time of the day may be, the trench must be laid enough ahead so that the fire may nearly reach but not cross it at the time the wind falls and the air currents change in the evening. Then, if the plans have been correctly laid and all dead trees that might fall across it have been cut, all will be well when evening falls. The wind will be down to a mere breeze which bears against the fire which is now burning nearly up to the trench. Back fires should then be set to all inflammable material immediately along the trench on the side toward the fire. Close watch should be kept that the fire may not get back across the trench; carried by the night breeze, it burns slowly toward the main fire. The two meet and the hard work is over.

Trustworthy men should be left to make their camp and stay with the fire that is inside the segregated area. A patrol of several days or even weeks is necessary so that a passing wind shall not carry embers over the line to start fires anew.

While the fires in the Rocky Mountain region are usually termed ground fires, it is a fact that within a fire area the crowns of nearly all trees are burned, and the shooting of the fire into the air and the burning of a large crown are fraught with serious possibilities of danger. A sharp lookout must always be kept, and in nearly every case a patrol must be maintained far beyond the trench construction to make sure that sparks and brands do not ignite the forest ahead and thus put the fires behind the fire instead of in front of it.

Fire control in the Pacific Northwest.—In the Pacific Northwest forest fires seldom travel with great rapidity, because the trees are less resinous than in other regions, but the luxuriant growth and great accumulation of duff and fallen wood makes them exceedingly difficult to extinguish. The monetary and economic loss is great because of the density and value of standing timber.

Even more than elsewhere is care with small fires of the greatest necessity, for the deep layer of combustible material on the ground may hold them for weeks or months until favorable conditions of wind and dry weather fan them into destructiveness. It too commonly happens that the arrival of such conditions late in every summer not only increases the danger from fires started while they prevail, but brings about the spreading beyond control of innumerable small fires which have been smouldering unattended because not considered dangerous under previous conditions when they could have been put out with small effort.

Camp fires should never be built against trees, logs, or rotten wood, which may remain burning unknown when the camp is left. Fires for clearing land should never be set during the dangerous season without the permit required by law and careful observance of its stipulated safeguards. Such fires set before the close season should be entirely extinguished or brought under complete control before the close season begins. Especially should all possible communication of smouldering fire from the burned area be prevented by the cutting of standing dead trees within it and the clearing of an adequate fire line around its edge. Accumulations of débris near cabins, logging camps, roads, and railroads should be burned at safe times in spring or fall, under the foregoing precautions, so they may not feed accidental fires during dry periods. Railroads or logging engines operating without proper spark arresters should be reported to the state authorities.

The tenacity of fires in the punklike ground cover is peculiar to this region. A fire starting in June may burn till Christmas in an area of one-fourth of an acre if the season is wet, but if a dry spell comes it spreads with great rapidity. There are thousands of such fires every year which nobody bothers with because they look so harmless, but when the right season comes the whole country burns up.

California.—Methods of fire protection and fire fighting in California do not differ materially from those in any other part of the West, except that protection must be more thorough and fighting must be done more quickly on account of the extraordinary dryness of the forest and the immense financial interests at stake. The long, hot summers, often without a drop of rain from May until November, turn the ground cover and underbrush into the most inflammable kind of material, and fire, once started, leaps along with amazing rapidity. This is especially true in the southern part of the State. Here the rich irrigated citrus lands are wholly dependent for their water supply on the brush-covered mountains from which the streams come. The chaparral of these slopes is so dense, so high, so dry, and so altogether impenetrable that when a fire once gets a good start it is almost impossible to control it. More than that, a man's life is in danger if he fails to keep at a safe distance.

The best protective measure is to make a network of trails, roads, and fire lines so that men can get about easily to watch for fire and get to it quickly when it starts; then during the danger season keep a lot of men constantly moving about the mountains ready to extinguish the little fires just as soon as they start; and give them a good telephone system by which to summon help when needed. These men must be professional fire fighters and know their business.

The best results in fighting forest fires will never be obtained until the whole thing is organized. This means hearty cooperation between the Federal Government, the several States, the counties, cities, corporations, and private owners; it means good laws, vigorously carried out, and it means the expenditure of money, a great deal of it.

(2) LEGISLATIVE MEASURES.

Practically all the States have laws fixing civil and criminal liability for damage done by the careless or malicious setting of forest fires. Recourse to these laws is, however, rare even in the States where the most advanced forest policies have been adopted. In the South laws of this kind are absolutely ignored. A strict enforcement of existing laws would go far toward removing the existing ignorance and indifference, and would, after a short time, render further prosecutions for the most part unnecessary.

Of great value, where properly enforced, are the laws prohibiting the setting of brush or fallow fires during certain seasons of the year, or allowing of such burning only upon the issuance of a special permit by a duly authorized officer, the burning to be done at such time and under such conditions as will not endanger neighboring forest property. Laws of this kind have been enacted in a number of the more progressive States. The proper enforcement of laws of this kind in the East and Middle West would prevent the occurrence of from one-third to one-half of the fires which occur under present conditions. In a letter to the forester in 1904, Col. W. F. Fox, of the New York state forest, fish, and game commission, said, referring to the New York fire law:

> I attach the most importance to the section of our law forbidding the farmers from burning brush or fallows in certain months of the year. Since the fires of a year ago we have enforced this law strictly in regard to the infliction of penalties for its violation. By continuing these prosecutions faithfully whenever a farmer burns his fallow out of season, we can undoubtedly eliminate entirely this prolific source of evil.

Nearly all the States have statutes requiring the use of efficient spark arresters on railroad locomotives. In general, however, the enforcement of these laws has been exceedingly lax, and in many cases engineers have not hesitated to remove the screens or to punch them full of holes when the presence of the screens began to interfere with the draft of the locomotive. Many railroad companies equip their locomotives with spark arresters, not because they are required to do so by state law, but in order to avoid civil suits for damages. This is the most effective weapon to compel observance of the law.

Many of the States also have laws requiring the clearing and annual burning of strips along rights of way. In only a very small number of cases is any attention paid to these laws. Strict enforcement, in connection with the use of efficient spark arresters, would bring about a great decrease in the number of forest fires along rights of way.

The great difficulty with laws such as those mentioned is that they are useless unless means are provided for their enforcement. This brings up the last and most important of the legislative measures for the prevention and control of forest fires, namely, the provision for an executive force charged with the duty of administering the laws. Many of the state forest and fire laws look exceedingly well on paper, but are totally inadequate to meet existing conditions, simply because inadequate machinery or none at all is provided for their enforcement. It should be fully recognized that it is cheaper to prevent forest fires than to fight them. The Federal Government has set the example by the establishment of a system of patrol on the national forests under the supervision of the Forest Service. Wherever possible, similar action should be taken by the States for the protection of state and private holdings from destruction by fire. There are several features which are essential to a good state fire law. In the first place an executive head should be provided. This should be a man who is thoroughly familiar with fire problems and who is intensely interested in the work. In some States this position is very advantageously combined with that of state forester; in others the two are kept separate, the firewarden being a nontechnical man. A good salary should be paid in order to secure a competent man. Political appointments should especially be avoided.

The second essential is the appointment of local firewardens. In most of the States where the appointment of firewardens is provided for this office has been combined with that of some township official, usually that of supervisor. It is believed, however, that the better policy is to appoint as firewardens the best men available and to make the positions permanent. Township officials, as a general rule, have a brief tenure of position, owing to the popular belief in rotation of office. In many cases also the town officials are apt to be petty politicians who are illy fitted for the important duties of fire protection and the management of large bodies of men. On the rolls of the State of New York are men who have served as firewardens over twenty years. Under this system they acquire an experience not only in fighting fire but in the exercise of judgment, the handling of men, and the keeping of the necessary accounts with the town and State. By confining appointments to property holders and influential citizens—men of well-known integrity—there is no need to fear that the firewardens will start fires to provide themselves with employment. They are too much interested in keeping down taxes in their respective towns to furnish any basis for this fear.

Without exception firewardens receive payment for time actually spent in fighting fire. Whether they should in addition receive a fixed salary to cover such duties as making reports and keeping records is open to question. Col. W. F. Fox, of the New York state forest, fish, and game commission, states:

> We do not find it necessary to pay the firewardens any fixed salary, large or small. We have had no difficulty in getting good men who were willing to serve without pay except for time and services actually rendered. As a rule our firewardens are well-to-do people who have lucrative employment the year round and do not need any compensation except for such time as when they are obliged by circumstances to give attention to the work. This is fortunate, because we have so many forest towns in our State that a salary list of this kind would be so burdensome that the taxpayers would complain. This would be the case especially in the years during which no fires occur.

On the other hand, Prof. F. Roth, forest warden for the State of Michigan, states:

> Even a forest warden should receive some pay, independent of whether he fights fire or not, at least enough to justify his attending to such duties as making reports and doing a certain amount of patrol work.

This plan has been put into effect in New Jersey, where township firewardens receive $20 and the district firewardens $10 annually, in addition to the per diem compensation allowed for time actually employed in fighting fire. The New Jersey plan has been in effect but a short time, so there has not been sufficient opportunity to demonstrate whether or not it is superior to the plan in effect in New York.

The great difficulty with practically all the firewarden systems, as at present in effect, is that they do not make adequate provision for the prevention of fires. In many cases the laws, if carried out, would provide a force to fight fires after they are once started. In practice, however, a firewarden is seldom informed concerning a small fire, so that in most cases he does not begin work until the fire has reached such proportions that it becomes a costly task to put it out. What is needed in forest regions is a system of paid patrol during the fire season. Small beginnings along this line have been made in several of the States, but they are almost entirely inadequate to meet the situation.

(3) EDUCATIVE MEASURES.

These are of primary importance, because it is through them that the adoption of administrative and legislative measures is secured. The most effective is the dissemination of information concerning the causes and effects of forest fires, and the methods by which they may be prevented or controlled. The almost total lack of accurate information concerning the loss due to forest fires is a very serious handicap to the efficacy of this method. Were the extent of the damage in its various forms once fully realized the public could not fail to be aroused to the point of taking decisive action.

On the ground, a very effective measure is the posting of fire notices at frequent intervals through the forest, particularly at camping places and at points of entrance and departure of travelers. These notices should be printed on cloth or tin, or be in the form of signs painted on wood. Cloth signs are usually about 12 by 14 inches in size and are ordinarily tacked on trees. They should be made to attract attention by the proper use of large type. Experience has shown that better results are obtained where cooperation is requested than where threats are used. Information should be given as to existing state or federal laws, and a brief statement made as to the reasons why the prevention of forest fires is desirable. The fire notice adopted by the Forest Service for use on the National Forests was designed to fulfill these requirements. The following is a copy:

FOREST FIRES.

The great annual destruction of forests by fire is an injury to all persons and industries. The welfare of every community is dependent upon a cheap and plentiful supply of timber and a forest cover is the most effective means of preventing floods and maintaining a regular flow of streams used for irrigation and other useful purposes.

To prevent forest fires Congress passed the law approved May 5, 1900, which—

FORBIDS SETTING FIRE TO THE WOODS, AND FORBIDS LEAVING ANY FIRES UNEXTINGUISHED.

This law, for offenses against which officers of the Forest Service can arrest without warrant, provides as maximum punishment—

A fine of $5,000 or imprisonment for two years, or both, if a fire is set maliciously, and a fine of $1,000 or imprisonment for one year, or both, if fire results from carelessness.

It also provides that the money from such fines shall be paid to the school fund of the county in which the offense is committed.

The exercise of care with small fires is the best preventive of large ones.—Therefore all persons are requested—

1. Not to build larger camp fires than are necessary.
2. Not to build fires in leaves, rotten wood, or other places where they are likely to spread.

3. In windy weather and in dangerous places to dig holes or clear the ground to confine camp fires.

4. To extinguish all fires completely before leaving them, even for a short absence.

5. Not to build fires against large or hollow logs where it is difficult to extinguish them.

6. Not to build fires to clear land without informing the nearest officer of the Forest Service, so that he may assist in controlling them.

This notice is posted for your benefit and the good of every resident of the region. You are requested to cooperate in preventing its removal or defacement, which acts are punishable by law.

JAMES WILSON,
Secretary of Agriculture.

(D) RESULTS ACCOMPLISHED.

(1) BY THE FEDERAL GOVERNMENT.

(*a*) NATIONAL FORESTS.

The increase in the efficiency of the national forest administration from year to year is strikingly shown by a comparison of the figures for area and value of timber destroyed during 1905, 1906, and 1907, as shown in the accompanying summary. The figure for 1907 was 42 per cent of that for 1906 and but 31 per cent of that for 1905. The percentage of total area burned over decreased from 0.66 of 1 per cent in 1904, before the Forest Service administration began, to 0.31 of 1 per cent in 1905; 0.094 of 1 per cent in 1906; and 0.14 of 1 per cent in 1907. The increase in area in 1907 is compensated for by the fact that all but 29,365 acres were grass fires, which destroyed no timber, while in 1906 the area of merchantable timber burned over was 52,374 acres. Thus in 1906 the merchantable forest burned over represented but one twenty-third of 1 per cent of the entire forest area, while in 1907 it was but one fiftieth of 1 per cent. These results have been brought about by the gradual increase in the number as well as in the efficiency of the rangers.

That the force is still much too small has been clearly demonstrated during the fire season of 1908. The season has, in general, been an exceedingly dry one, and fire losses over the entire country have been greater than at any time for many years. The expenditure of approximately $50,000 for fire fighting on the national forests has been necessary, in addition to salaries of forest officers under appointment, as contrasted with less than one-tenth of that amount during the preceding year. While the fire losses have been much heavier than during any other year since the forest service administration began, yet they are infinitesimal as compared with what was saved. It is estimated that of the 167,992,208 acres in the national forests, 75,000,000 acres contain saw timber of commercial size. The stand of timber on this area is estimated at nearly 400 billion feet board measure. At the average rate of $2.50 per M stumpage, the timber on the national forests thus has a value of $1,000,000,000. The wisdom of spending a reasonable amount of money for the protection of this vast property of the people can not be questioned.

The following tables show fire losses on the national forests since 1902, so far as statistics are available from the Forest Atlas:

Area of national forests in the United States, exclusive of Alaska and Porto Rico, burned over from 1904 to 1907, inclusive.

[Statistics from Forest Atlas and Boundaries Record.]
